Fundamental Programming
Concepts Expressed in JavaScript
Overview: Programming Concepts

- Programming: Act of formulating an algorithm or program
- Basic concepts have been developed over last 50 years to simplify common programming tasks
- Concepts will be expressed in JavaScript
Programming Concepts

- Names, values, variables
- Declarations
- Data types, numbers, string literals and Booleans
- Assignment
- Expressions
- Conditionals, or branches
At the Espresso Stand

Espresso is concentrated liquid coffee produced by passing steam through finely ground coffee beans. Some people enjoy drinking espresso straight, but others prefer a café latté, espresso in steamed milk; a cappuccino, espresso in equal parts of steamed milk and milk foam; or an Americano, espresso in near-boiling water. Espresso drinks are sold in three sizes: short (8 oz.), tall (12 oz.), and grande (16 oz.). These drinks are made with a single unit of espresso, called a shot, but coffee addicts often order additional shots. The price of additional shots is added to the base price of the drink, and tax is figured in to produce the charge for the drink. The program to compute the price of an espresso drink is:

Input:
drink, a character string with one of the values: "espresso", "latte",
   "cappuccino", "Americano"
ounce, an integer, giving the size of the drink in ounces
shots, an integer, giving the number of shots

Output:
price in dollars of an order, including 8.8% sales tax

Figure 18.1. Sample JavaScript computation to figure the cost of espresso drinks. (continues next page).
Program:

```javascript
var price;
var taxRate = 0.088;
if (drink == "espresso")
    price = 1.40;
if (drink == "latte" || drink == "cappuccino") {
    if (ounce == 8)
        price = 1.95;
    if (ounce == 12)
        price = 2.35;
    if (ounce == 16)
        price = 2.75;
}
if (drink == "Americano")
    price = 1.20 + .30 * (ounce/8);
price = price + (shots - 1) * .50;
price = price + price * taxRate;
```

Figure 18.1 (continued). Sample JavaScript computation to figure the cost of espresso drinks.
Names, Values, and Variables

• Names Have Changing Values
  * Example: U.S. President has current value of George W. Bush, previous values of Bill Clinton, George Washington

• Names in a Program Are Called Variables
  * Values associated with a name change in programs using the assignment statement (something = something else)
Identifiers and Their Rules

- Identifier is the character sequence that makes up a variable's name

  * Must have a particular form
    * Must begin with a letter or underscore ( _ ) followed by any sequence of letters, digits, or underscore characters
    * Cannot contain spaces
    * Case sensitive (Capitalization matters!)
Identifiers and Their Rules

<table>
<thead>
<tr>
<th>Valid</th>
<th>Invalid</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstOne</td>
<td>1stOne</td>
</tr>
<tr>
<td>first1</td>
<td>first-1</td>
</tr>
<tr>
<td>first_1</td>
<td>first$1</td>
</tr>
<tr>
<td>first_One</td>
<td>first One</td>
</tr>
<tr>
<td>FirstOne</td>
<td>First1!</td>
</tr>
</tbody>
</table>
A Variable Declaration Statement

• Declaration: State what variables will be used
  * Command is the word `var`
  * For example, a program to calculate area of circle given radius, needs variables area and radius:
    • `var radius, area;`

• The declaration is a type of statement
The Statement Terminator

• A program is a list of statements
• The statements may be run together on a line
  * Use whatever spacing you need to read your code and understand your program
• Each statement is terminated by the statement terminator symbol
  * In JavaScript, all statements terminate with the semicolon ( ; )
Names, Values, And Variables

• Declaring a variable
  * Names a particular area in computer memory where you can store values
  * Gives you a name, or handle, that is independent of the current value
Rules for Declaring Variables

- Every variable used in a program must be declared (before it is used)
  - In JavaScript, declaration can be anywhere in the program
  - Programmers prefer to place them first

- Undefined values
  - Variable has been declared but does not yet have a value
    ```javascript
    var number1; // undefined value
    var number2 = 42; // initialized to the value 42
    ```
Initializing a Declaration

• We can set an initial value as part of declaration statement:
  * var taxRate = .088;

• Related variables may be grouped in one declaration(initialization); unrelated variables are usually placed in separate statements

  var num1 = 42, num2, num3;
  var num1 = 42;
  var num2;
  var num3;
Three Basic Date Types of Javascript

- Numbers
- Strings
- Booleans

* These kind of values are called data types or just types
• Rules for Writing Numbers

* There are no "units" or commas

* Can have about 10 significant digits and can range from $10^{-324}$ to $10^{308}$
Strings

- Strings are sequences of keyboard characters
- Strings are always surrounded by single ( ' ' ) or double quotes ( " " )
  - No smart quotes!
- Strings can initialize a declaration
  - var hairColor = "black";
- Quotes can nest
  - firstLine = "Johnson called, ‘Dude!’"
Strings

• Rules for Writing Strings
  * Must be surrounded by single or double quotes
  * Allow most characters except return (Enter), backspace, tab, \n  * Double-quoted strings can contain single quoted strings and vice versa
  * The apostrophe ( ' ) is the same as the single quote
  * Any number of characters allowed in a string
  * Minimum number of characters is zero ( "" ), which is the empty string
Literals

• String Literals stored in the computer
  * Quotes are removed (they are only used to delimit the string literal)
  * Any character can be stored in memory
    • Even a character that cannot be typed can be stored, using escape mechanism – in JavaScript, the backslash (\)
**Table 18.1** Escape sequences for characters prohibited from string literals

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Character</th>
<th>Sequence</th>
<th>Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>Backspace</td>
<td>\f</td>
<td>Form feed</td>
</tr>
<tr>
<td>\n</td>
<td>New line</td>
<td>\r</td>
<td>Carriage return</td>
</tr>
<tr>
<td>\t</td>
<td>Tab</td>
<td>'</td>
<td>Apostrophe or single quote</td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quote</td>
<td>\\</td>
<td>Backslash</td>
</tr>
</tbody>
</table>
Comments

- **HTML**
  ```html
  <!-- HTML comments -->
  ```

- **JavaScript**
  ```javascript
  // Single-line JavaScript comment
  /* Multi-line JavaScript comment continues for more than one line */
  ```
Boolean Values

- Two logical values: True and False
- They are values, not identifiers or strings
- Used implicitly throughout programming process; only occasionally for initializing variables
  - Mostly used to compare data or make decisions
Assigning Values to Variables

• Assign values to variables with an assignment operator.

• We'll use = for now.

```javascript
var yourAge, acctBal, custName
yourAge = 32; //store 32 in yourAge
acctBal = 100.75; //store 100.75 in acctBal
custName = 'Jeff'; //store 'Jeff' in custName
isCustomer = true; //store boolean true in isCustomer (no quotes)
var yourName = 'Jeff' //alternate all-in-one line assignment statement
```
Assignment Statement

\(<\text{Variable}> <\text{assignment}><\text{expression}>\)

- Flow moves from right to left.
- Results of the \(<\text{expression}>\) replace the value stored in the \(<\text{variable}>\).
# Assigning Values to Variables and Variables to Variables

We can also assign one variable to another:

<table>
<thead>
<tr>
<th>Line</th>
<th>Assignment Statement</th>
<th>myName</th>
<th>yourName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>var yourName = &quot;Sarah&quot;;</td>
<td></td>
<td>Sarah</td>
</tr>
<tr>
<td>2</td>
<td>var myName = &quot;Andrea&quot;;</td>
<td>Andrea</td>
<td>Sarah</td>
</tr>
<tr>
<td>3</td>
<td>var yourName = myName;</td>
<td>Andrea</td>
<td>Andrea</td>
</tr>
<tr>
<td>4</td>
<td>var yourName = &quot;myName&quot;;</td>
<td>Andrea</td>
<td>myName</td>
</tr>
</tbody>
</table>

10-23-2007  
D.A. Clements, Instructor
## Other Assignment Operators

<table>
<thead>
<tr>
<th>Line</th>
<th>Assignment Statement</th>
<th>Value in myAge</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>var myage = 32;</code></td>
<td>32</td>
</tr>
<tr>
<td>2</td>
<td><code>myAge = myAge + 2;</code></td>
<td>34</td>
</tr>
<tr>
<td>3</td>
<td><code>myAge += 2;</code></td>
<td>36</td>
</tr>
<tr>
<td>4</td>
<td><code>myAge += 2;</code></td>
<td>37</td>
</tr>
<tr>
<td>5</td>
<td><code>myAge -= 3;</code></td>
<td>34</td>
</tr>
<tr>
<td>6</td>
<td><code>myAge -;</code></td>
<td>33</td>
</tr>
</tbody>
</table>
Assignment

• Three Key Points
  * All three of the components must be given
    • if anything is missing, the statement is meaningless
  * Flow of value to identifier is always right to left
  * Values of any variables used in the expression are always their values before the start of the execution of the assignment
An Expression and its Syntax

- Algebra-like formula called an expression
  - Describe the means of performing the actual computation
  - Built out of values and operators
    - Standard arithmetic operators are symbols of basic arithmetic
Arithmetic Operators

- Multiplication must be given explicitly with the asterisk (*) multiply operator
- Multiply and divide are performed before add and subtract
  - Unless grouped by parentheses
  - Within parentheses multiply and divide are performed first
- JavaScript does not have an operator for exponents
- Binary operators operate on two operands (like + and *)
- Unary operators operate on one operand (like - for negate)
- Modulus or mod (%) divides two integers and returns the remainder
Relational Operators

- Make comparisons between numeric values
- Outcome is a Boolean value, true or false
- < less than
- <= less than or equal to
- == equal to
  (Note difference between = and ==)
- != not equal to
- >= greater than or equal to
- > greater than
Logical Operators

- **To test two or more relationships together**
  - Teenagers are older than 12 and younger than 20

- **Logical AND**
  - Operator is `&&`
  - Outcome of `a && b` is true if both `a` and `b` are true; otherwise it is false

- **Logical OR**
  - Operator is `||`
  - Outcome of `a || b` is true if either `a` is true or `b` is true

- **Logical NOT**
  - Operator is `!`
  - Unary operator. Outcome is opposite of value of operand
Operator Overload

- Use of an operator with different data types
- Case of interest in JavaScript is +

Addition

- When used with numbers, + adds
  - 4 + 5 produces 9

Concatenation

- When + is used with strings, + concatenates or joins the strings together
  - "four" + "five" produces "fourfive"
A Conditional Statement

if ( <Boolean expression> )
<then-statement>;

• Boolean expression is a relational expression; then-statement is any JavaScript statement
If Statements and Their Flow of Control

- The Boolean statement, called a predicate, is evaluated, producing a true or false outcome.
- If the outcome is true, the then-statement is performed.
- If the outcome is false, the then-statement is skipped.
- Then-statement can be written on the same line as the Boolean or on the next line.
Compound Statements

- Sometimes we need to perform more than one statement on a true outcome of the predicate test.
- You can have a sequence of statements in the then clause.
- Group these statements using curly braces {}.
  * They are collected as a compound statement.
if/else Statements

• To execute statements if a condition is false
  
  ```
  if ( <Boolean expression> )
  {
    <then-statements>;
  }
  else
  {
    <else-statements>;
  }
  
  The Boolean expression is evaluated first
  * If the outcome is true, the then-statements are executed and the else-statements are skipped
  * If the outcome is false, the then-statements are skipped and the else-statements are executed
  ```

18-38
Nested if/else Statements

- The then-statement and the else-statement can contain an if/else
- The else is associated with the immediately preceding if
- Correct use of curly braces ensures that the else matches with its if
Nested if/else Statements

if (<Boolean exp1>)
  if (<Boolean exp2>)
  {
    <then-stmts for exp2>;
  }
else
  {
    <else-stmts for exp2>;
  }

if (<Boolean exp1>)
  {
    if (<Boolean exp2>)
    {
      <then-stmts for exp2>;
    }
  }
else
  {
    <else-stmts for exp2>;
  }
The Espresso Program

Input:
- drink, a character string with one of the values: "espresso", "latte", "cappuccino", "Americano"
- ounce, an integer, giving the size of the drink in ounces
- shots, an integer, giving the number of shots

Output:
- price in dollars of an order, including 8.8% sales tax

Program:
1. var price;
2. var taxRate = 0.088;
3. if (drink == "espresso")
   price = 1.40;
4. if (drink == "latte" || drink == "cappuccino") {
   4a. if (ounce == 8)
       price = 1.95;
   4b. if (ounce == 12)
       price = 2.35;
   4c. if (ounce == 16)
       price = 2.75;
   }
5. if (drink == "Americano")
   price = 1.20 + .30 * (ounce/8);
6. price = price + (shots - 1) * .50;
7. price = price + price * taxRate;
The Espresso Program

- Line 3 is a basic conditional statement
- Lines 4-4c use an if statement with conditionals in the then statement
- Line 5 uses basic if statement
- Lines 6, 7 compute using arithmetic operators
Summary

Programming is the exact specification of an algorithm.

JavaScript is typical ... with many rules.

- **Learning strategy**
  - Do the reading first
  - Practicing is better than memorizing for learning the rules
  - Use the program-save-reload-check plan
  - Precision is your best friend
