

# Building Java Programs

## Chapter 3

Lecture 3-2: `Return; double; System.out.printf`

**reading: 3.2, 3.5, 4.4**

videos: Ch. 3 #2, 4

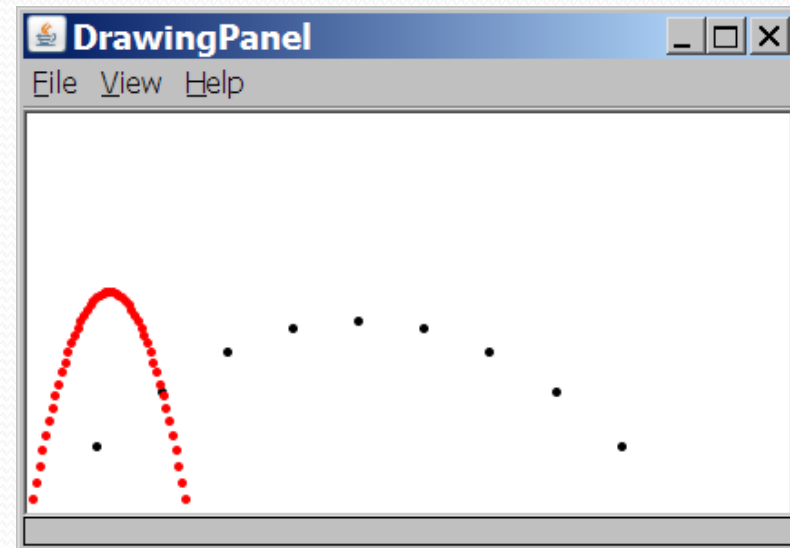

# Projectile problem

- Write a program that displays (as text and graphics) the paths of projectiles thrown at various velocities and angles.
  - Projectile #1: velocity = 60, angle = 50°, steps = 10
  - Projectile #2: velocity = 50, angle = 80°, steps = 50

step	x	y	time
0	0.00	0.00	0.00
1	36.14	38.76	0.94
2	72.28	68.91	1.87
3	108.42	90.45	2.81
4	144.56	103.37	3.75
5	180.70	107.67	4.69
6	216.84	103.37	5.62
7	252.98	90.45	6.56
8	289.12	68.91	7.50
9	325.26	38.76	8.43
10	361.40	0.00	9.37

step	x	y	time
0	0.00	0.00	0.00
1	1.74	9.69	0.20
2	3.49	18.98	0.40

...

# Return Values

**reading: 3.2**

self-check: #7-11

exercises: #4-6

videos: Ch. 3 #2

# Java's Math class

Method name	Description
<code>Math.abs(<i>value</i>)</code>	absolute value
<code>Math.round(<i>value</i>)</code>	nearest whole number
<code>Math.ceil(<i>value</i>)</code>	rounds up
<code>Math.floor(<i>value</i>)</code>	rounds down
<code>Math.log10(<i>value</i>)</code>	logarithm, base 10
<code>Math.max(<i>value1</i>, <i>value2</i>)</code>	larger of two values
<code>Math.min(<i>value1</i>, <i>value2</i>)</code>	smaller of two values
<code>Math.pow(<i>base</i>, <i>exp</i>)</code>	<i>base</i> to the <i>exp</i> power
<code>Math.sqrt(<i>value</i>)</code>	square root
<code>Math.sin(<i>value</i>)</code> <code>Math.cos(<i>value</i>)</code> <code>Math.tan(<i>value</i>)</code>	sine/cosine/tangent of an angle in radians
<code>Math.toDegrees(<i>value</i>)</code> <code>Math.toRadians(<i>value</i>)</code>	convert degrees to radians and back
<code>Math.random()</code>	random double between 0 and 1

Constant	Description
<code>Math.E</code>	2.7182818...
<code>Math.PI</code>	3.1415926...

# Calling Math methods

`Math.methodName (parameters)`

- Examples:

```
double squareRoot = Math.sqrt(121.0);  
System.out.println(squareRoot);           // 11.0
```

```
int absoluteValue = Math.abs(-50);  
System.out.println(absoluteValue);        // 50
```

```
System.out.println(Math.min(3, 7) + 2);   // 5
```

- The `Math` methods do not print to the console.
  - Each method produces ("returns") a numeric result.
  - The results are used as expressions (printed, stored, etc.).

# Return

- **return:** To send out a value as the result of a method.
  - The opposite of a parameter:
    - Parameters send information *in* from the caller to the method.
    - Return values send information *out* from a method to its caller.

# Math Mini-Exercises #1

- Evaluate the following expressions:
  - `Math.abs(-1.23)`
  - `Math.pow(3, 2)`
  - `Math.pow(10, -2)`
  - `Math.sqrt(25.0) - Math.sqrt(9.0)`

<b>Method name</b>	<b>Description</b>
<code>Math.abs(<i>value</i>)</code>	absolute value
<code>Math.pow(<i>base</i>, <i>exp</i>)</code>	<i>base</i> to the <i>exp</i> power
<code>Math.sqrt(<i>value</i>)</code>	square root

# Math Mini-Exercises - Solutions

- Evaluate the following expressions:
  - `Math.abs(-1.23)`  $\Rightarrow$  1.23
  - `Math.pow(3, 2)`  $\Rightarrow$  9.0
  - `Math.pow(10, -2)`  $\Rightarrow$  0.01
  - `Math.sqrt(25.0) - Math.sqrt(9.0)`  $\Rightarrow$  2.0

Method name	Description
<code>Math.abs(<i>value</i>)</code>	absolute value
<code>Math.pow(<i>base</i>, <i>exp</i>)</code>	<i>base</i> to the <i>exp</i> power
<code>Math.sqrt(<i>value</i>)</code>	square root

# Math Mini-Exercises #2

- `Math.max` and `Math.min` can be used to bound numbers. Consider an `int` variable named `age`.
  - What statement would replace negative ages with 0?
  - What statement would cap the maximum age to 40?

Method name	Description
<code>Math.max(<i>value1</i>, <i>value2</i>)</code>	larger of two values
<code>Math.min(<i>value1</i>, <i>value2</i>)</code>	smaller of two values

# Math Mini-Exercises #2 - Solutions

- `Math.max` and `Math.min` can be used to bound numbers. Consider an `int` variable named `age`.
  - What statement would replace negative ages with 0?  
`age = Math.max(age, 0);`
  - What statement would cap the maximum age to 40?  
`age = Math.min(age, 40);`

# Returning a value

```
public static type name (parameters) {  
    statements;  
    ...  
    return expression;  
}
```

- Example:

```
// Returns the slope of the line between the given points.  
public static double slope(int x1, int y1, int x2, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    return dy / dx;  
}
```

# Return examples

**// Converts Fahrenheit to Celsius.**

```
public static double fToC(double degreesF) {  
    double degreesC = 5.0 / 9.0 * (degreesF - 32);  
    return degreesC;  
}
```

**// Computes triangle hypotenuse length given its side lengths.**

```
public static double hypotenuse(int a, int b) {  
    double c = Math.sqrt(a * a + b * b);  
    return c;  
}
```

- You can shorten the examples by returning an expression:

```
public static double fToC(double degreesF) {  
    return 5.0 / 9.0 * (degreesF - 32);  
}
```

# Common error: Not storing

- Many students incorrectly think that a `return` statement sends a variable's name back to the calling method.

```
public static void main(String[] args) {  
    slope(0, 0, 6, 3);  
    System.out.println("The slope is " + result); // ERROR:  
} // result not defined
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

# Fixing the common error

- Instead, returning sends the variable's *value* back.
  - The returned value must be stored into a variable or used in an expression to be useful to the caller.

```
public static void main(String[] args) {  
    double s = slope(0, 0, 6, 3);  
    System.out.println("The slope is " + s);  
}
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

# Quirks of real numbers

- Some Math methods return double or other non-int types.

```
int x = Math.pow(10, 3);    // ERROR: incompat. types
```

- Some double values print poorly (too many digits).

```
double result = 1.0 / 3.0;  
System.out.println(result);    // 0.3333333333333333
```

- The computer represents doubles in an imprecise way.

```
System.out.println(0.1 + 0.2);
```

- Instead of 0.3, the output is 0.30000000000000004

# Type casting

- **type cast:** A conversion from one type to another.
  - To promote an `int` into a `double` to get real-number division from the `/` operator
  - To truncate a `double` from a real number to an integer

- Syntax:

**(type) expression**

Examples:

```
double result = (double) 19 / 5;           // 3.8
int result2 = (int) result;                // 3
int x = (int) Math.pow(10, 3);            // 1000
```

# More about type casting

- Type casting has high precedence and only casts the item immediately next to it.
  - `double x = (double) 1 + 1 / 2; // 1`
  - `double y = 1 + (double) 1 / 2; // 1.5`
- You can use parentheses to force evaluation order.
  - `double average = (double) (a + b + c) / 3;`
- A conversion to `double` can be achieved in other ways.
  - `double average = 1.0 * (a + b + c) / 3;`

# System.out.printf

*an advanced command for printing formatted text*

```
System.out.printf ("format string", parameters);
```

- A format string contains *placeholders* to insert parameters into it:
  - %d            an integer
  - %f            a real number
  - %s            a string

- Example:

```
int x = 3;
```

```
int y = 2;
```

```
System.out.printf (" (%d, %d) \n", x, y);    // (3, 2)
```

# System.out.printf cont'd

- A placeholder can specify the parameter's *width* or *precision*:
  - %8d an integer, 8 characters wide, right-aligned
  - %-8d an integer, 8 characters wide, left-aligned
  - %.4f a real number, 4 characters after decimal
  - %6.2f a real number, 6 characters wide, 2 after decimal

- Examples:

```
int age = 45;  
double gpa = 1.2345678;
```

```
System.out.printf("%-8d %4f\n", age, gpa);  
System.out.printf("%8.3f %.1f %.5f", gpa, gpa, gpa);
```

- Output:

```
45          1.23  
          1.234 1.2 1.23457
```

# System.out.printf

## Mini-exercises

- Write a statement that prints "pi = " followed by pi to 6 decimal places (use `Math.PI` to obtain the value of pi)
- Write a statement that prints a double `x` to 6 decimal places and that includes 10 characters total (including leading spaces as needed)
- Cheat sheet:  
A placeholder can specify the parameter's *width* or *precision*:
  - `%8d` an integer, 8 characters wide, right-aligned
  - `%-8d` an integer, 8 characters wide, left-aligned
  - `%.4f` a real number, 4 characters after decimal
  - `%6.2f` a real number, 6 characters wide, 2 after decimal

# System.out.printf

## Mini-exercises - solutions

- Write a statement that prints "pi = " followed by pi to 6 decimal places (use `Math.PI` to obtain the value of pi)

```
System.out.printf("pi = %.6f", Math.PI);
```

- Write a statement that prints a double `x` to 6 decimal places and that includes 10 characters total (including leading spaces as needed)

```
System.out.printf("%10.6f", x);
```

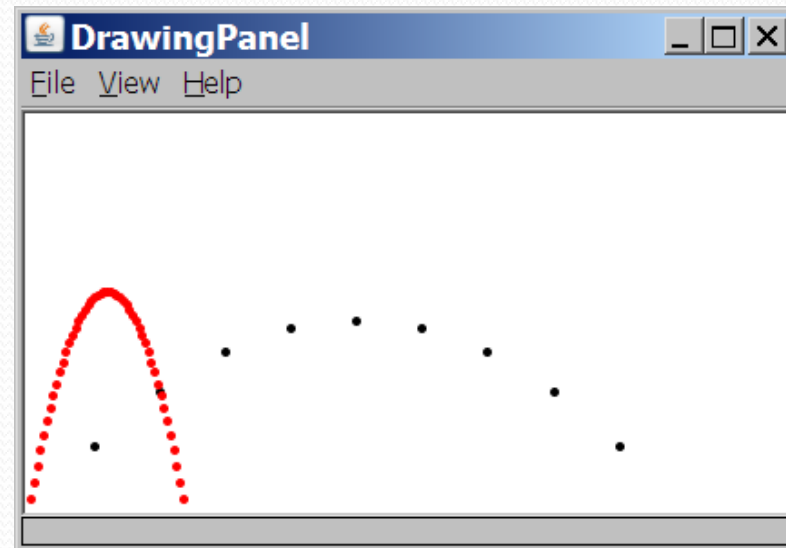

# Projectile problem revisited

- *Recall:* Display (as text and graphics) the paths of projectiles thrown at various velocities and angles.
  - Projectile #1: velocity = 60, angle = 50°, steps = 10
  - Projectile #2: velocity = 50, angle = 80°, steps = 50

step	x	y	time
0	0.00	0.00	0.00
1	36.14	38.76	0.94
2	72.28	68.91	1.87
3	108.42	90.45	2.81
4	144.56	103.37	3.75
5	180.70	107.67	4.69
6	216.84	103.37	5.62
7	252.98	90.45	6.56
8	289.12	68.91	7.50
9	325.26	38.76	8.43
10	361.40	0.00	9.37

step	x	y	time
0	0.00	0.00	0.00
1	1.74	9.69	0.20
2	3.49	18.98	0.40

...

# Time observations

- We are given the number of "steps" of time to display.
  - We must figure out how long it takes the projectile to hit the ground, then divide this time into the # of steps requested.

step	x	y	time
0	0.00	0.00	0.00
1	36.14	38.76	0.94
2	72.28	68.91	1.87
...			
10	361.40	0.00	9.37

- Total time is based on the force of gravity on the projectile.
  - Force of gravity ( $g$ )  $\rightarrow$  9.81 m/s<sup>2</sup>, downward
  - The projectile has an initial upward velocity, which is fought by gravity until the projectile reaches its peak, then it falls.

# Velocity and acceleration

- The projectile has a given initial velocity  $v_0$ , which can be divided into x and y components.

- $v_{0x} = v_0 \cos \Theta$

- $v_{0y} = v_0 \sin \Theta$

- Example: If  $v_0=13$  and  $\Theta=60^\circ$ ,  $v_{0x}=12$  and  $v_{0y}=5$ .

- The velocity  $v_t$  of a moving body at time  $t$ , given initial velocity  $v_0$  and acceleration  $a$ , can be expressed as:
  - $v_t = v_0 + a t$
- In our case, because of symmetry, at the end time  $t$  the projectile is falling exactly as fast as it was first going up.
  - $v_{ty} = -v_{0y}$
  - $-v_{0y} = v_{0y} + a t$
  - $t = -2 v_{0y} / a$

# X/Y position, displacement

- Based on the previous, we can now display  $x$  and *time*.
  - $x_t = v_x t$  since there is no force in the  $x$  direction.

step	x	y	time
0	0.00	????	0.00
1	36.14	????	0.94
2	72.28	????	1.87
...			
10	361.40	????	9.37

- To display the  $y$ , we need to compute the projectile's *displacement* in  $y$  direction at each time increment.
  - $y_t = v_{0y} t + \frac{1}{2} a t^2$
  - Since this formula is complicated, let's make it into a method.

# Projectile solution

```
// This program computes and draws the trajectory of a projectile.

import java.awt.*;

public class Projectile {
    // constant for Earth's gravity acceleration in meters/second^2
    public static final double ACCELERATION = -9.81;

    public static void main(String[] args) {
        DrawingPanel panel = new DrawingPanel(420, 250);
        Graphics g = panel.getGraphics();

        //          v0  angle  steps
        table(g, 60, 50, 10);

        g.setColor(Color.RED);
        table(g, 50, 80, 50);
    }

    // returns the displacement for a body under acceleration
    public static double displacement(double v0, double t, double a) {
        return v0 * t + 0.5 * a * t * t;
    }

    ...
}
```

# Projectile solution

...

```
// prints a table showing the trajectory of an object given
// its initial velocity v and angle and number of steps
public static void table(Graphics g, double v0,
                        double angle, int steps) {
    double v0x = v0 * Math.cos(Math.toRadians(angle));
    double v0y = v0 * Math.sin(Math.toRadians(angle));
    double totalTime = -2.0 * v0y / ACCELERATION;
    double dt = totalTime / steps;

    System.out.println("    step        x        y        time");
    for (int i = 0; i <= steps; i++) {
        double time = i * dt;
        double x = i * v0x * dt;
        double y = displacement(v0y, time, ACCELERATION);
        System.out.printf("%8d%8.2f%8.2f%8.2f\n", i, x, y, time);
        g.fillOval((int) x, (int) (250 - y), 5, 5);
    }
}
}
```
