

# Building Java Programs

Chapter 7  
Lecture 7-2: Arrays as Parameters

**reading: 7.1 – 7.3**

# Array reversal question

- Write code that reverses the elements of an array.
  - For example, if the array initially stores:  
[11, 42, -5, 27, 0, 89]
  - Then after your reversal code, it should store:  
[89, 0, 27, -5, 42, 11]
    - The code should work for an array of any size.
    - Hint: think about swapping various elements...

# Algorithm idea

- Swap pairs of elements from the edges; work inwards:

<i>index</i>	0	1	2	3	4	5
<i>value</i>	89	0	27	-5	42	11
	↑	↑	↑	↑	↑	↑

# Swapping values

```
public static void main(String[] args) {  
    int a = 7;  
    int b = 35;  
// swap a with b?  
a = b;  
b = a;  
    System.out.println(a + " " + b);  
}
```

- What is wrong with this code? What is its output?
- The red code should be replaced with:

```
int temp = a;  
a = b;  
b = temp;
```

# Flawed algorithm

- What's wrong with this code?

```
int[] numbers = [11, 42, -5, 27, 0, 89];  
// reverse the array  
for (int i = 0; i < numbers.length; i++) {  
    int temp = numbers[i];  
    numbers[i] = numbers[numbers.length - 1 - i];  
    numbers[numbers.length - 1 - i] = temp;  
}
```

- The loop goes too far and un-reverses the array! Fixed version:

```
for (int i = 0; i < numbers.length / 2; i++) {  
    int temp = numbers[i];  
    numbers[i] = numbers[numbers.length - 1 - i];  
    numbers[numbers.length - 1 - i] = temp;  
}
```

# Array reverse question 2

- Turn your array reversal code into a `reverse` method.
  - Accept the array of integers to reverse as a parameter.

```
int[] numbers = {11, 42, -5, 27, 0, 89};  
reverse(numbers);
```

- How do we write methods that accept arrays as parameters?
  - Will we need to return the new array contents after reversal?

...

# Array parameter (declare)

```
public static type methodName(type [ ] name) {
```

- Example:

```
// Returns the average of the given array of numbers.  
public static double average(int [ ] numbers) {  
    int sum = 0;  
    for (int i = 0; i < numbers.length; i++) {  
        sum += numbers[i];  
    }  
    return (double) sum / numbers.length;  
}
```

- You don't specify the array's length (but you can examine it).

# Array parameter (call)

**methodName (arrayName) ;**

- Example:

```
public class MyProgram {  
    public static void main(String[] args) {  
        // figure out the average TA IQ  
        int[] iq = {126, 84, 149, 167, 95};  
        double avg = average(iq);  
        System.out.println("Average IQ = " + avg);  
    }  
    ...  
}
```

- Notice that you don't write the [] when passing the array.

# Array return (declare)

```
public static type[] methodName(parameters) {
```

- Example:

```
// Returns a new array with two copies of each value.  
// Example: [1, 4, 0, 7] -> [1, 1, 4, 4, 0, 0, 7, 7]  
public static int[] repeat(int[] numbers) {  
    int[] result = new int[2 * numbers.length];  
    for (int i = 0; i < numbers.length; i++) {  
        result[2 * i] = numbers[i];  
        result[2 * i + 1] = numbers[i];  
    }  
    return result;  
}
```

# Array return (call)

```
type [ ] name = methodName(parameters) ;
```

- Example:

```
public class MyProgram {  
    public static void main(String[] args) {  
        int[] iq = {126, 84, 149, 167, 95};  
        int[] doubled = repeat(iq);  
        System.out.println(Arrays.toString(doubled));  
    }  
    ...  
}
```

- Output:

```
[126, 126, 84, 84, 149, 149, 167, 167, 95, 95]
```

# Reference semantics

**reading: 7.3**

# A swap method?

- Does the following swap method work? Why or why not?

```
public static void main(String[] args) {  
    int a = 7;  
    int b = 35;  
  
    // swap a with b?  
    swap(a, b);  
  
    System.out.println(a + " " + b);  
}
```

```
public static void swap(int a, int b) {  
    int temp = a;  
    a = b;  
    b = temp;  
}
```

# Value semantics

- **value semantics:** Behavior where values are copied when assigned, passed as parameters, or returned.
  - All primitive types in Java use value semantics.
  - When one variable is assigned to another, its value is copied.
  - Modifying the value of one variable does not affect others.

```
int x = 5;  
int y = x;      // x = 5, y = 5  
y = 17;          // x = 5, y = 17  
x = 8;          // x = 8, y = 17
```

# Reference semantics (objects)

- **reference semantics:** Behavior where variables actually store the address of an object in memory.
  - When one variable is assigned to another, the object is *not* copied; both variables refer to the *same object*.
  - Modifying the value of one variable *will* affect others.

```
int[] a1 = {4, 15, 8};  
int[] a2 = a1;           // refer to same array as a1  
a2[0] = 7;  
System.out.println(Arrays.toString(a1)); // [7, 15, 8]
```

# Value/Reference Semantics

- Variables of primitive types store values directly:

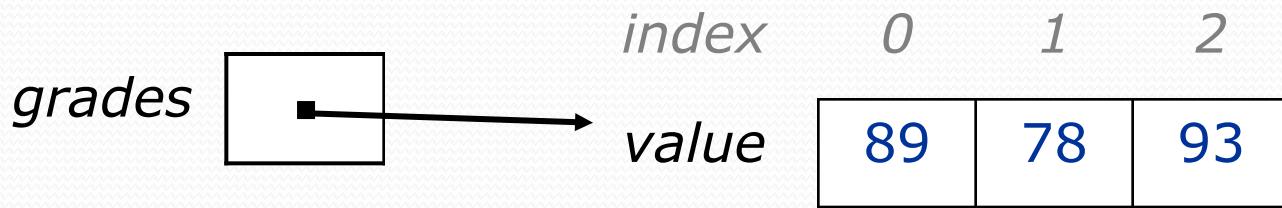

- Values are copied from one variable to another:

*cats* = *age*;

- Variables of object types store references to memory:

- References are copied from one variable to another:

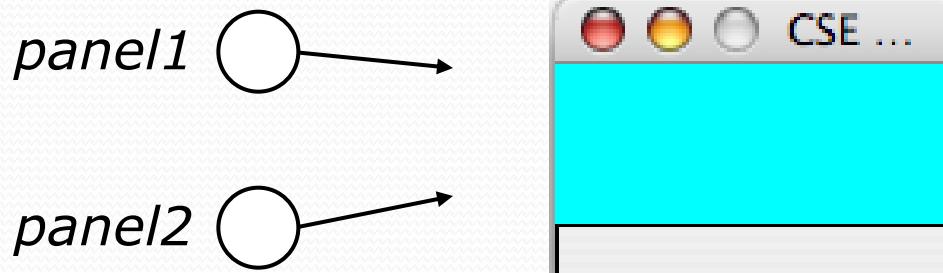

*scores* = *grades*;

# References and objects

- Arrays and objects use reference semantics. Why?
  - *efficiency.* Copying large objects slows down a program.
  - *sharing.* It's useful to share an object's data among methods.

```
DrawingPanel panel1 = new DrawingPanel(80, 50);  
DrawingPanel panel2 = panel1; // same window  
panel2.setBackground(Color.CYAN);
```

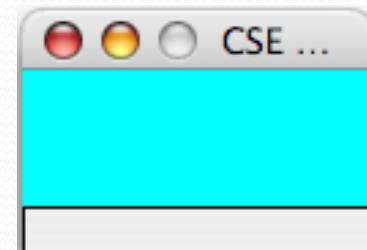

# Objects as parameters

- When an object is passed as a parameter, the object is *not* copied. The parameter refers to the same object.
  - If the parameter is modified, it *will* affect the original object.

```
public static void main(String[] args) {  
    DrawingPanel window = new DrawingPanel(80, 50);  
    window.setBackground(Color.YELLOW);  
    example(window);                                window  
}  
                                         ↓
```

```
public static void example(DrawingPanel panel) {  
    panel.setBackground(Color.CYAN);  
    ...  
}
```

panel →

# Arrays pass by reference

- Arrays are passed as parameters by *reference*.
  - Changes made in the method are also seen by the caller.

```
public static void main(String[] args) {  
    int[] iq = {126, 167, 95};  
    increase(iq);  
    System.out.println(Arrays.toString(iq));    iq  
}  
  
public static void increase(int[] a) {  
    for (int i = 0; i < a.length; i++) {  
        a[i] = a[i] * 2;  
    }  
}
```

- Output:  
[252, 334, 190]

<i>index</i>	0	1	2
<i>a</i>	252	334	190
<i>value</i>			

# Array reverse question 2

- Turn your array reversal code into a `reverse` method.
  - Accept the array of integers to reverse as a parameter.

```
int[] numbers = {11, 42, -5, 27, 0, 89};  
reverse(numbers);
```

- Solution:

```
public static void reverse(int[] numbers) {  
    for (int i = 0; i < numbers.length / 2; i++) {  
        int temp = numbers[i];  
        numbers[i] = numbers[numbers.length - 1 - i];  
        numbers[numbers.length - 1 - i] = temp;  
    }  
}
```

# Array parameter questions

- Write a method `swap` that accepts an array of integers and two indexes and swaps the elements at those indexes.

```
int[] a1 = {12, 34, 56};  
swap(a1, 1, 2);  
System.out.println(Arrays.toString(a1)); // [12, 56, 34]
```

- Write a method `swapAll` that accepts two arrays of integers as parameters and swaps their entire contents.

- Assume that the two arrays are the same length.

```
int[] a1 = {12, 34, 56};  
int[] a2 = {20, 50, 80};  
swapAll(a1, a2);  
System.out.println(Arrays.toString(a1)); // [20, 50, 80]  
System.out.println(Arrays.toString(a2)); // [12, 34, 56]
```

# Array parameter answers

```
// Swaps the values at the given two indexes.  
public static void swap(int[] a, int i, int j) {  
    int temp = a[i];  
    a[i] = a[j];  
    a[j] = temp;  
}  
  
// Swaps the entire contents of a1 with those of a2.  
public static void swapAll(int[] a1, int[] a2) {  
    for (int i = 0; i < a1.length; i++) {  
        int temp = a1[i];  
        a1[i] = a2[i];  
        a2[i] = temp;  
    }  
}
```

# Array return question

- Write a method `merge` that accepts two arrays of integers and returns a new array containing all elements of the first array followed by all elements of the second.

```
int[] a1 = {12, 34, 56};  
int[] a2 = {7, 8, 9, 10};  
int[] a3 = merge(a1, a2);  
System.out.println(Arrays.toString(a3));  
// [12, 34, 56, 7, 8, 9, 10]
```

- Write a method `merge3` that merges 3 arrays similarly.

```
int[] a1 = {12, 34, 56};  
int[] a2 = {7, 8, 9, 10};  
int[] a3 = {444, 222, -1};  
int[] a4 = merge3(a1, a2, a3);  
System.out.println(Arrays.toString(a4));  
// [12, 34, 56, 7, 8, 9, 10, 444, 222, -1]
```

# Array return answer 1

```
// Returns a new array containing all elements of a1
// followed by all elements of a2.
public static int[] merge(int[] a1, int[] a2) {
    int[] result = new int[a1.length + a2.length];
    for (int i = 0; i < a1.length; i++) {
        result[i] = a1[i];
    }
    for (int i = 0; i < a2.length; i++) {
        result[a1.length + i] = a2[i];
    }
    return result;
}
```

# Array return answer 2

```
// Returns a new array containing all elements of a1,a2,a3.  
public static int[] merge3(int[] a1, int[] a2, int[] a3) {  
    int[] a4 = new int[a1.length + a2.length + a3.length];  
    for (int i = 0; i < a1.length; i++) {  
        a4[i] = a1[i];  
    }  
    for (int i = 0; i < a2.length; i++) {  
        a4[a1.length + i] = a2[i];  
    }  
    for (int i = 0; i < a3.length; i++) {  
        a4[a1.length + a2.length + i] = a3[i];  
    }  
    return a4;  
}
```

```
// Shorter version that calls merge.  
public static int[] merge3(int[] a1, int[] a2, int[] a3) {  
    return merge(merge(a1, a2), a3);  
}
```
