Building Java Programs

Chapter 3
Lecture 3-1: Parameters and Scope

reading: 3.1
I have written all the whole numbers from 1 to 1000! By hand. Just now.

It's okay! Jealousy is the natural reaction.

It's not actually that impressive, T-Rex. I figure I've PROBABLY done it, just as a matter of course!

Oh, sure, "probably"! But I have CERTAINLY done it, because I sat down and did it. It only took an hour, and now I don't have to live with doubt or uncertainty. I don't have to live with probably!

I fail to see the benefit!

Um, I DOUBLE CHECKED THE NUMBER SYSTEM?

I have verified by brute force that all these numbers exist AND can be written! Don't worry, mathematicians, the whole number series has been verified secure up to 1000... thanks to ME.

For i=1 to 1000, print i, loop

ERROR 5000: NOT ACTUALLY A COMPUTER, UTAHRAPTOR

(C) 2012 Ryan North
**Scope**

- **scope**: The part of a program where a variable exists.
  - From its declaration to the end of the `{ }` braces
    - A variable declared in a `for` loop exists only in that loop.
    - A variable declared in a method exists only in that method.

```java
public static void example() {
    int x = 3;
    for (int i = 1; i <= 10; i++) {
        System.out.println(x);
    }
    // i no longer exists here
}
// x ceases to exist here
```
Promoting reuse

• Programmers build increasingly complex applications
  • Enabled by existing building blocks, e.g. methods

• The more general a building block, the easier to reuse

• Abstraction: focusing on essential properties rather than implementation details

• Algebra is all about abstraction
  • Functions solve an entire class of similar problems
Redundant recipes

• Recipe for baking **20** cookies:
  • Mix the following ingredients in a bowl:
    • 4 cups flour
    • 1 cup butter
    • 1 cup sugar
    • 2 eggs
    • 40 oz. chocolate chips ...
  • Place on sheet and Bake for about **10** minutes.

• Recipe for baking **40** cookies:
  • Mix the following ingredients in a bowl:
    • 8 cups flour
    • 2 cups butter
    • 2 cups sugar
    • 4 eggs
    • 80 oz. chocolate chips ...
  • Place on sheet and Bake for about **10** minutes.
Parameterized recipe

• Recipe for baking 20 cookies:
  • Mix the following ingredients in a bowl:
    • 4 cups flour
    • 1 cup sugar
    • 2 eggs
    • ...

• Recipe for baking N cookies:
  • Mix the following ingredients in a bowl:
    • \( \frac{N}{5} \) cups flour
    • \( \frac{N}{20} \) cups butter
    • \( \frac{N}{20} \) cups sugar
    • \( \frac{N}{10} \) eggs
    • 2N oz. chocolate chips ...
  • Place on sheet and Bake for about 10 minutes.

• parameter: A value that distinguishes similar tasks.
Redundant figures

- Consider the task of printing the following lines/boxes:

```
*************

**********

*        *
```

```
***********************************

**********

*****

*   *

*   *

*****
```

```
*       *

*       *

*       *
```

```
*   *

*   *

*   *

*   *
```

```
*  *

*  *

*  *

*  *

*  *

*  *
```
A redundant solution

This code is redundant.

Would variables help? Would constants help?

What is a better solution?

- line - A method to draw a line of any number of stars.
- box - A method to draw a box of any size.
Parameterization

- **parameter**: A value passed to a method by its caller.

- Instead of `lineOf7`, `lineOf13`, write `line` to draw any length.
  - When *declaring* the method, we will state that it requires a parameter for the number of stars.
  - When *calling* the method, we will specify how many stars to draw.
Declaring a parameter

Stating that a method requires a parameter in order to run

```
public static void <name> (<type> <name>) {
     <statement>(s);
}
```

• **Example:**
  ```
  public static void favoriteNumber(int num) {
      ...
  }
  ```

• When `favoriteNumber` is called, the caller must specify the integer code to print.
Passing a parameter

Calling a method and specifying values for its parameters

```
(name)(<expression>);
```

- Example:
  ```java
  public static void main(String[] args) {
    favoriteNumber(42);
    favoriteNumber(12345);
  }
  ```

Output:

Favorite number is 42
Favorite number is 12345
Using a parameter

Parameter is a local variable that can be used throughout the method by its name

- Example:

  ```java
  public static void favoriteNumber(int num) {
      System.out.println("Favorite number is: " + num);
  }
  
  - When `favoriteNumber` is called, parameter `num` is a local variable declared and is initialized to the value given by the caller
Parameters and loops

- A parameter can guide the number of repetitions of a loop.

```java
public static void main(String[] args) {
    chant(3);
}

public static void chant(int times) {
    for (int i = 1; i <= times; i++) {
        System.out.println("Just a salad...");
    }
}
```

Output:
Just a salad...
Just a salad...
Just a salad...
How parameters are passed

- When the method is called:
  - The value is stored into the parameter variable.
  - The method's code executes using that value.

```java
public static void main(String[] args) {
    chant(3);
    chant(7);
}

public static void chant(int times) {
    for (int i = 1; i <= times; i++) {
        System.out.println("Just a salad...");
    }
}
```
Common errors

- If a method accepts a parameter, it is illegal to call it without passing any value for that parameter.
  
  ```
  chant(); // ERROR: parameter value required
  ```

- The value passed to a method must be of the correct type.
  
  ```
  chant(3.7); // ERROR: must be of type int
  ```

- Exercise: Change the Stars program to use a parameterized method for drawing lines of stars.
// Prints several lines of stars.
// Uses a parameterized method to remove redundancy.
public class Stars2 {
    public static void main(String[] args) {
        line(13);
        line(7);
        line(35);
    }

    // Prints the given number of stars plus a line break.
    public static void line(int count) {
        for (int i = 1; i <= count; i++) {
            System.out.print("*");
        }
        System.out.println();
    }
}
Multiple parameters

- A method can accept multiple parameters. (separate by , )
  - When calling it, you must pass values for each parameter.

- Declaration:
  ```java
  public static void <name>(<type> <name>, ..., <type> <name>)
  {
      <statement>(s);
  }
  ```

- Call:
  ```java
  <name>(<exp>, <exp>, ..., <exp>);
  ```
Multiple parameters example

```java
public static void main(String[] args) {
    printNumber(4, 9);
    printNumber(17, 6);
    printNumber(8, 0);
    printNumber(0, 8);
}

public static void printNumber(int number, int count) {
    for (int i = 1; i <= count; i++) {
        System.out.print(number);
    }
    System.out.println();
}

Output:
444444444
171717171717
00000000

- Modify the Stars program to draw boxes with parameters.
// Prints several lines and boxes made of stars.
// Third version with multiple parameterized methods.

class Stars3 {
    public static void main(String[] args) {
        line(13);
        line(7);
        line(35);
        System.out.println();
        box(10, 3);
        box(5, 4);
        box(20, 7);
    }

    // Prints the given number of stars plus a line break.
    public static void line(int count) {
        for (int i = 1; i <= count; i++) {
            System.out.print("*");
        }
        System.out.println();
    }

    ...
}
Stars solution, cont'd.

...
Value semantics

- **value semantics**: When primitive variables (`int`, `double`) are passed as parameters, their values are copied.
- Modifying the parameter will not affect the variable passed in.

```java
public static void strange(int x) {
    x = x + 1;
    System.out.println("1. x = " + x);
}

public static void main(String[] args) {
    int x = 23;
    strange(x);
    System.out.println("2. x = " + x);
    ...
}
```

Output:
1. x = 24
2. x = 23
A "Parameter Mystery" problem

```java
public class ParameterMystery {
    public static void main(String[] args) {
        int x = 9;
        int y = 2;
        int z = 5;

        mystery(z, y, x);
        mystery(y, x, z);
    }

    public static void mystery(int x, int z, int y) {
        System.out.println(z + " and " + (y - x));
    }
}
```
Strings

- **string**: A sequence of text characters.

```java
String <name> = "<text>";
String <name> = <expression resulting in String>;
```

- **Examples:**

```java
String name = "Marla Singer";
int x = 3;
int y = 5;
String point = "(" + x + ", " + y + ")";
```
Strings as parameters

```java
public class StringParameters {
    public static void main(String[] args) {
        sayHello("Marty");
        String teacher = "Bictolia";
        sayHello(teacher);
    }

    public static void sayHello(String name) {
        System.out.println("Welcome, " + name);
    }
}
```

Output:

Welcome, Marty
Welcome, Bictolia

- Modify the Stars program to use string parameters. Use a method named `repeat` that prints a string many times.
public class Stars4 {
    public static void main(String[] args) {
        line(13);
        line(7);
        line(35);
        System.out.println();
        box(10, 3);
        box(5, 4);
        box(20, 7);
    }

    // Prints the given number of stars plus a line break.
    public static void line(int count) {
        repeat("*", count);
        System.out.println();
    }

    ...
Stars solution, cont'd.

...  

// Prints a box of stars of the given size.
public static void box(int width, int height) {
    line(width);
    for (int line = 1; line <= height - 2; line++) {
        System.out.print("*");
        repeat(" ", width - 2);
        System.out.println("*");
    }
    line(width);
}

// Prints the given String the given number of times.
public static void repeat(String s, int times) {
    for (int i = 1; i <= times; i++) {
        System.out.print(s);
    }
}
