CSE 143

Lecture 11: Sets and Maps

reading: 11.2 - 11.3

SUBSTITUTIONS THAT MAKE READING THE NEWS MORE FUN:

WITNESSES THESE DUDES I KNOW
ALLEGEDLY> KINDA PROBABLY
NEW STUDY> TUMBLR POST
REBUILD AVENGE
SPACE> SPAAACE
GOOGLE GLASS> VIRTUAL BOY
SMARTPHONE> POKÉDEX
ELECTRIC ATOMIC
SENATOR> ELF-LORD
car —— Cat
ELECTION> EATING CONTEST
CONGRESSIONAL LEADERS RIVER SPIRITS
HOMELAND SECURITY HOMESTAR RUNNER
COULD NOT BE REACHED IS GUILTY AND
FOR COMMENT EVERYONE KNOWS IT

The "for each" loop (7.1) for (type name : collection) { statements; }

 Provides a clean syntax for looping over the elements of a Set, List, array, or other collection

```
Set<Double> grades = new HashSet<Double>();
```

```
for (double grade : grades) {
    System.out.println("Student's grade: " + grade);
}
```

needed because sets have no indexes; can't get element i

Exercise

- Write a program to <u>count the number of occurrences</u> of each unique word in a large text file (e.g. *Moby Dick*).
 - Allow the user to type a word and report how many times that word appeared in the book.
 - Report all words that appeared in the book at least 500 times, in alphabetical order.
- What collection is appropriate for this problem?

Maps (11.3)

- map: Holds a set of unique keys and a collection of values, where each key is associated with one value.
 - a.k.a. "dictionary", "associative array", "hash"
- basic map operations:
 - put(key, value): Adds a mapping from a key to a value.
 - get(key): Retrieves the value mapped to the key.
 - remove(key): Removes the given key and its mapped value.

myMap.get("Juliet") returns "Capulet"

Map implementation

- in Java, maps are represented by Map type in java.util
- Map is implemented by the HashMap and TreeMap classes
 - HashMap: implemented using an array called a "hash table"; extremely fast: O(1); keys are stored in unpredictable order
 - TreeMap: implemented as a linked "binary tree" structure; very fast: O(log N); keys are stored in sorted order
 - LinkedHashMap: O(1); keys are stored in order of insertion
- A map requires 2 type params: one for keys, one for values.

// maps from String keys to Integer values
Map<String, Integer> votes = new HashMap<String, Integer>();

Map methods

put(key, value)	adds a mapping from the given key to the given value; if the key already exists, replaces its value with the given one
get (key)	returns the value mapped to the given key (null if not found)
containsKey(key)	returns true if the map contains a mapping for the given key
remove(key)	removes any existing mapping for the given key
clear()	removes all key/value pairs from the map
size()	returns the number of key/value pairs in the map
isEmpty()	returns true if the map's size is 0
toString()	returns a string such as " $\{a=90, d=60, c=70\}$ "
keySet()	returns a set of all keys in the map
values()	returns a collection of all values in the map
putAll(map)	adds all key/value pairs from the given map to this map
equals(map)	returns true if given map has the same mappings as this one

Using maps

• A map allows you to get from one half of a pair to the other.

• Remembers one piece of information about every index (key).

Maps and tallying

- a map can be thought of as generalization of a tallying array
 - the "index" (key) doesn't have to be an int
 - count digits: 22092310907

keys

values

keySet and values

- keySet method returns a Set of all keys in the map
 - can loop over the keys in a foreach loop
 - can get each key's associated value by calling get on the map

```
Map<String, Integer> ages = new TreeMap<String, Integer>();
ages.put("Marty", 19);
ages.put("Geneva", 2); // ages.keySet() returns Set<String>
ages.put("Vicki", 57);
for (String name : ages.keySet()) { // Geneva -> 2
    int age = ages.get(name); // Marty -> 19
    System.out.println(name + " -> " + age); // Vicki -> 57
}
```

- values method returns a collection of all values in the map
 - can loop over the values in a foreach loop
 - no easy way to get from a value to its associated key(s)
