

Building Java Programs

Binary Search Trees; TreeSet

Recall: $x = \text{change}(x)$

- Methods that modify a tree should have the following pattern:
 - input (parameter): old state of the node
 - output (return): new state of the node

- In order to actually change the tree, you must reassign:

```
node.left = change(node.left, parameters);  
node.right = change(node.right, parameters);  
overallRoot = change(overallRoot, parameters);
```

Exercise

- Add a method `getMin` to the `IntTree` class that returns the minimum integer value from the tree. Assume that the elements of the `IntTree` constitute a legal binary search tree. Throw a `NoSuchElementException` if the tree is empty.

```
int min = tree.getMin(); // -3
```

Exercise solution

```
// Returns the minimum value from this BST.  
// Throws a NoSuchElementException if the tree is empty.  
public int getMin() {  
    if (overallRoot == null) {  
        throw new NoSuchElementException();  
    }  
    return getMin(overallRoot) ;  
}
```

```
private int getMin(IntTreeNode root) {  
    if (root.left == null) {  
        return root.data;  
    } else {  
        return getMin(root.left);  
    }  
}
```

Exercise

- Add a method `remove` to the `IntTree` class that removes a given integer value from the tree, if present. Remove the value in such a way as to maintain BST ordering.

- `tree.remove(73);`
- `tree.remove(29);`
- `tree.remove(87);`
- `tree.remove(55);`

Cases for removal 1

1. a **leaf**:

replace with `null`

2. a node with a **left child only**:

replace with left child

3. a node with a **right child only**:

replace with right child

```
tree.remove(-3);
```

```
tree.remove(55);
```

```
tree.remove(29);
```

Cases for removal 2

4. a node with **both** children: replace with **min from right**
- (replacing with max from left would also work)

`tree.remove(55);`

Exercise solution

```
// Removes the given value from this BST, if it exists.
public void remove(int value) {
    overallRoot = remove(overallRoot, value);
}

private IntTreeNode remove(IntTreeNode root, int value) {
    if (root == null) {
        return null;
    } else if (root.data > value) {
        root.left = remove(root.left, value);
    } else if (root.data < value) {
        root.right = remove(root.right, value);
    } else { // root.data == value; remove this node
        if (root.right == null) {
            return root.left; // no R child; replace w/ L
        } else if (root.left == null) {
            return root.right; // no L child; replace w/ R
        } else {
            // both children; replace w/ min from R
            root.data = getMin(root.right);
            root.right = remove(root.right, root.data);
        }
    }
    return root;
}
}
```

Searching BSTs

- The BSTs below contain the same elements.
 - What orders are "better" for searching?

Trees and balance

- **balanced tree:** One whose subtrees differ in height by at most 1 and are themselves balanced.
 - A balanced tree of N nodes has a height of $\sim \log_2 N$.
 - A very unbalanced tree can have a height close to N .
- The runtime of adding to / searching a BST is closely related to height.
- Some tree collections (e.g. `TreeSet`) contain code to balance themselves as new nodes are added.
