Question 1 - Part A

After the following lines of code are printed, what values are stored in the set output_set?

```python
input_list = [3,1,4,1,5,9,2,6,5,3,5,9]
output_set = set([])
for i in input_list:
    output_set.add(i)
```

Question 2

In one line of code, print the set of all numbers that are in both the sets. (i.e. - their intersection)

```python
set_one = {'a', 'b', 'c', 'd', 'e', 'f'}
set_two = {'a', 'c', 'd', 'g'}
```

Question 3

Given the following code:

```python
weather = {
    'Monday':{'low':45,'high':62,'precipitation':0.3},
    'Tuesday':{'low':48,'high':69,'precipitation':0.2},
    'Wednesday':{'low':42,'high':58,'precipitation':0.5}
}
```

What does the following code print:

```python
print weather['Monday']['high']
print weather['Tuesday'][0]
print weather['Wednesday']
```
Question 4

For each of the following questions, implement a function that returns the answer to the question. For each question, follow this procedure:

1. Identify a good name for the function.
2. Identify the return value.
3. Identify any necessary parameters.
4. Write the function definition.
5. Write the function’s docstring.
6. Describe, on paper, in words, or in your head, the algorithm you’ll use to solve the problem.
7. Implement the function.

Effective programmers perform these steps for every program they write, and they solve them very quickly. Ineffective programmers often make the mistake of mixing steps 6 and 7, either skipping step 6 or performing 6 and 7 simultaneously. As mentioned in lecture, the most effective programmers start coding later, and finish earlier. This is because they understood the problem and its solution before ever writing code.

You may assume that every function takes as a parameter a data structure with the same structure as the following.

```json
[{
  'Company': 'Apple', 'Date': '01 Jan 2010', 'Purpose': 'payroll', 'Cost': 95},
{'Company': 'Microsoft', 'Date': '01 Feb 2010', 'Purpose': 'payroll', 'Cost': 1000},
{'Company': 'Microsoft', 'Date': '16 June 2010', 'Purpose': 'philanthropy', 'Cost': 250},
{'Company': 'Google', 'Date': '11 Dec 2010', 'Purpose': 'legal', 'Cost': 110},
{'Company': 'Apple', 'Date': '30 Aug 2010', 'Purpose': 'building renovations', 'Cost': 10000},
{'Company': 'Google', 'Date': '29 Dec 2010', 'Purpose': 'equipment', 'Cost': 25},
{'Company': 'Microsoft', 'Date': '01 Feb 2010', 'Purpose': 'payroll', 'Cost': 1000},
{'Company': 'Oracle', 'Date': '01 Jan 2010', 'Purpose': 'payroll', 'Cost': 30},
... More rows, with more companies, dates, purposes, and costs ...
]
```

You are allowed to use the solutions from previous problems to solve later problems.

1. For a given company, how much did that company spend in total?
2. For a given company, how much did that company spend on payroll?
3. What are all the companies that made expenditures?
4. Which company spent the least in total?
5. What are the evil companies, if any, that didn’t have any payroll expenditures (and so clearly aren’t paying their employees).

When you’ve finished this function, do a Google search on "google motto".

CSE 140 Section 3 Solutions

Question 1 - Part A
{1, 6, 3, 9, 5, 2, 4}
* Remember sets are unordered, so the order of the values above has no significance

Question 2
set_one & set_two
The intersection is: {'a', 'c', 'd'}

Question 3
62
KeyError: 0
{'low':42,'high':58,'precipitation':0.5}

Question 3
For a given company, how much did that company spend in total?
def total_costs(expenditures, company):
    '''
    Given a company’s name (string) and a list of expenditure reports, returns the total expenditures for that company.
    '''
    total = 0
    for item in expenditures:
        if item['Company'] == company:
            total += item['Cost']
    return total

For a given company, how much did that company spend on payroll?

def payroll_costs(expenditures, company):
    '''
    Given a company’s name (string) and a list of expenditures, returns the total payroll expenditures for that company.
    '''
    total = 0
    for item in expenditures:
        if item['Company'] == company and item['Purpose'] == 'payroll':
            total = total + item['Cost']
    return total

What are all the companies that made expenditures?

def all_companies(expenditures):
    '''
    Given a list of expenditures, returns a set of all the companies that had expenditures.
    '''
    companies = set()
    for item in expenditures:
        companies.add(item['Company'])
    return companies
Which company spent the least in total?

def lowest_costs(expenditures):
    ""
    Given a list of expenditure reports, returns the name of the company
    that spent the least money.
    ""

    # Get a set of all companies
    companies = all_companies(expenditures)

    # Get a dictionary from a company to that company’s expenditures
    costs = {}
    for company in companies:
        costs[company] = total_costs(expenditures, company)

    # Keep a running min of the lowest expenditures
    min_name = None
    for company_name in costs:
        if min_name == None or costs[company_name] < costs[min_name]:
            min_name = company_name
    return min_name

What are the evil companies, if any, that didn’t have any payroll expenditures
(and so clearly aren’t paying their employees). When you’ve finished this
function, do a Google search on "google motto".

def evil_companies(expenditures):
    ""
    Returns a set of evil companies (the ones that aren’t paying their
    employees, the scum-sucking corporate jerks).
    ""

    companies = all_companies(expenditures)

    payrolls = {}
    for company in companies:
        payrolls[company] = payroll_costs(expenditures, company)

    evil_companies = set()
    for company in payrolls:
        if payrolls[company] == 0:
            evil_companies.add(company)

    return evil_companies
