The Python interpreter

CSE 160 University of Washington Ruth Anderson

Two ways to run Python

- The Python interpreter
 - You type one expression at a time
 - The interpreter evaluates the expression and prints its value
- Running a Python program
 - Python evaluates all the statements in the file, in order
 - Python does not print their values (but does execute print statements)
 - Writing an expression outside a statement (assignment, print, etc.) is useless, unless it is a function call that has a side effect

The Python interpreter

The interpreter is a loop that does:

- Read an expression
- Evaluate the expression
- Print the result

If the result is **None**, the interpreter does not print it This inconsistency can be confusing!

(Jargon: An interpreter is also called a "readeval-print loop", or a REPL)

How to launch the Python interpreter

Two ways to launch the interpreter:

- Run Canopy; in the window labeled "Python" you should see:
 - "Welcome to Canopy's interactive data-analysis environment!"
 - This window is a Python interpreter called the ipython shell*
- Type **python** or **ipython** at the operating system command line
 - Type exit() to return to the operating system command line

These are not the same:

- Operating system command line, or "shell" or "command prompt" (cmd.exe under Windows) or "terminal"
 - Runs programs (Python, others), moves around the file system
 - Does not understand Python code like 1+2 or x = 22
- Python interpreter
 - Executes Python statements and expressions
 - Does not understand program names like **python** or **cd**

* The **ipython** shell is what is shown in Canopy. You can access either the **python** shell or the **ipython** shell from the operating system command line. The **ipython** shell has more features than the **python** shell, but both are Python interpreters.

Running a Python program

- Python evaluates each statement one-by-one
- Python does no extra output, beyond print statements in the program
- Two ways to run a program:
 - While editing a program within Canopy:
 - press the green triangle/play button
 - Hit Control and the letter R at the same time
 - Select the menu item "Run >> Run File"
 - Type at operating system command line:
 python myprogram.py

Python interpreter vs. Python program

- Running a Python file as a program gives different results from pasting it line-by-line into the interpreter
 - The interpreter prints more output than the program would
- In the Python interpreter, evaluating a top-level expression prints its value
 - Evaluating a sub-expression generally does not print any output
 - The interpreter does not print a value for an expression that evaluates to None
 - This is primarily code that is executed for side effect: assignments, print statements, calls to "non-fruitful" functions
- In a Python program, evaluating an expression generally does not print any output

Side effects vs. results

- Some Python code is executed because it has a useful value (72 - 32) * 5.0 / 9 math.sqrt(3*3 + 4*4)
- Some Python code is executed because it has a side effect print "hello"
 - $\mathbf{x} = 22$
- A function (call) can be of either variety
 - Think Python calls a function that returns a value a "fruitful function"
 - A function that only prints some text is non-fruitful
 - A function should either return a value, or have a side effect
 - It is bad style for a function to do both
 - Printing a value is *completely different* from returning it
- When the code is executed for a side effect, its value is None
