# Introduction to Python and programming 

Andrew S. Fitz Gibbon
UW CSE 160
Winter 2022

1. Python is a calculator

2. Different types cannot be compared

3. A variable is a container

4. A program is a recipe

CORNBREAD

## Colvin Run Mill Corn Bread

1 cup cornmeal
1 cup flour
$1 / 2$ teaspoon salt
4 teaspoons baking powder
3 tablespoons sugar
1 egg
1 cup milk
$1 / 4$ cup shortening (soft) or vegetable oil
Mix together the dry ingredients. Beat together the egg,
milk and shortening/oil. Add the liquids to the dry ingredients Mix quickly by hand. Pour into greased $8 \times 8$ or $9 \times 9$ baking pan. Bake at 425 degrees for $20-25$ minutes.

## O. Don't panic!

- CSE 160 is for beginners to programming
- (If you know how to program, you don't belong)
- You can learn to program in 10 weeks
- You will work hard
- We will work hard to help you
- Ask questions!
- This is the best way to learn

## 1. Python is a calculator

## You type expressions.

## Python computes their values.

- 5
- $3+4$
- 44 / 2
- 2 ** 3
- 3 * $4+5$ * 6
- If precedence is unclear, use parentheses
- (72-32) / $9 * 5$

## An expression is evaluated from the inside out

- How many expressions are in this Python code?

$(72-32) / 9.0 * 5$
(40) / 9.0 * 5

40 / 9.0 * 5
4.44 * 5
22.2

## Another evaluation example

(72-32) / (9.0 * 5)
(40) / (9.0 * 5)
$40 /(9.0$ * 5$)$
40 / (45.0)
40 / 45.0
. 888

## 2. A variable is a container

## Variables hold values

- Recall variables from algebra:
- Let $\mathrm{x}=2$...
- Let $\mathrm{y}=\mathrm{x}$...
- In Python: "varname = expression"
pi $=3.14$
Nothing printed from an assignment statement

An expression that can be
typed into a python
avogadro $=6 * 10 * * 23$ interpreter to be evaluated. avogadro Not a statement to put into a python program.
\# Error!

- Not all variable names are permitted

## ("re-binding" or "re-assigning")

X
y

Nothing printed from an assignment statement

An expression that can be typed into a python interpreter to be evaluated. Not a statement to put into a python program.

- "=" in an assignment is not a promise of eternal equality
- This is different than the mathematical meaning of "="
- Evaluating an expression gives a new (copy of a) number, rather than changing an existing one

## How an assignment is executed

1. Evaluate the right-hand side to a value
2. Store that value in the variable

| $x=2$ |
| :--- |
| $\operatorname{print}(x)$ |
| $y=x$ |
| $\operatorname{print}(y)$ |
| $z=x+1$ |
| $\operatorname{print}(z)$ |
| $x=5$ |
| $\operatorname{print}(x)$ |
| $\operatorname{print}(y)$ |
| $\operatorname{print}(z)$ |

State of the computer:
Printed output:

To visualize a program's execution: http://pythontutor.com A custom link to this program is here

## How an assignment is executed

1. Evaluate the right-hand side to a value
2. Store that value in the variable
$x=2$
print (x)
$y=x$
print (y)
$z=x+1$
print(z)
$x=5$
print (x)
print (y)
print(z)

State of the computer:

Printed output:

To visualize a program's execution: http://pythontutor.com A custom link to this program is here
$22>4$
$22<4$
$22=4$
$x=100$
$22=4$
x >= 5
$x>=100$
$x>=200$
not True
not (x >= 200)
$3<4$ and $5<6$
$4<3$ or $5<6$
temp $=72$
water_is_liquid $=$ temp $>32$ and temp $<212^{3}$

Also: see a program printing these expressions in python tutor
\# Assignment, not conditional! \# Error!

Order of Precedence:
Numeric operators: +, *, ** Mixed operators: <, >=, == Boolean operators: not, and, or

## What do you think?

What is printed out by the following Python code:

1) print(2<7 or $3>12)$
2) print(not $((2<3)$ and $(4>100)))$
3) 
```
temp = 72
    is_liquid = temp > 32 and temp < 212
    print(is_liquid)
    temp = 300
    print(is_liquid)
```

## More expressions: strings

A string represents text
'Python'
this_class = "CSE 160"
" "
Empty string is not the same as an unbound variable
Operations on strings:

- Length:
len(this_class)
- Concatenation:
"Andrew" + "S" + 'Fitz' + "Gibbon"
- Containment/searching:
'0' in this_class
"O" in this_class

## 3. Different types cannot be compared

## Types of values

- Integers (int): -22, 0, 44
- Arithmetic is exact
- Real numbers (float): 2.718, 3.1415
- float, for "floating point"
- Arithmetic is approximate
- Strings (str): "I love Python", ""
- Truth values (bool):

True, False

- bool, for "Boolean"

## Operations behave differently on different types

$3.0+4.0$
$3+4$
$3+4.0$
"3" + "4"
$3+44 "$
$3+$ True

Also: see a program printing these
expressions in python tutor
\# Error
\# Don't do this.

Moral: Python sometimes tells you when you do something that does not make sense.

## Operations behave differently on different types

$15.0 / 4.0$
15 / 4 \# Would have been truncated in Python 2.
$15.0 / 4$
15 / 4.0

See a program printing these expressions in python tutor

Type conversion:
float(15)
int(15.0)
int(15.5)
int("15")
str (15.5)
float(15) / 4

## 4. A program is a recipe

## CORNBREAD

```
Colvin Run Mill Corn Bread
1 cup cornmeal
1 cup flour
\(1 / 2\) teaspoon salt
4 teaspoons baking powder
3 tablespoons sugar
1 egg
1 cup milk
\(1 / 4\) cup shortening (soft) or vegetable oil
```

Mix together the dry ingredients. Beat together the egg, milk and shortening/oil. Add the liquids to the dry ingredients.
Mix quickly by hand. Pour into greased $8 \times 8$ or $9 \times 9$ baking pan.
Bake at 425 degrees for 20-25 minutes.

## What is a program?

- A program is a sequence of instructions
- The computer executes one after the other, as if they had been typed to the interpreter
- Saving your work as a program is better than retyping from scratch
$\mathbf{x}=1$
$y=2$
$x+y$
print $(x+y)$
print("The sum of", $x$, "and", $Y$, "is", $x+y$ )

## Interlude: The print statement

- The print statement always prints one line
- The next print statement prints below that one
- Write 0 or more expressions inside the parentheses, separated by commas
- In the output, the values are separated by spaces
- Examples:
print(3.1415)
print(2.718, 1.618)
print()
print(20 + 2, 7 * 3, 4 * 5)
print("The sum of", $x$, "and", $y, ~ " i s ", ~ x+\underset{22}{ }$ )

## Expressions, statements, and programs

- An expression evaluates to a value
$3+4$
pi * r ** 2
- A statement causes an effect
pi $=3.14159$
print(pi)
- Expressions appear within other expressions and within statements
(fahr - 32) * (5.0 / 9)
print(pi * r ** 2)
- A statement may not appear within an expression

3 + print(pi) \#Error!

- A program is made up of statements
- A program should do something or communicate information
- Just evaluating an expression does not accomplish either goal

1. Python is a calculator

2. Different types cannot be compared

3. A variable is a container

4. A program is a recipe

CORNBREAD

## Colvin Run Mill Corn Bread

1 cup cornmeal
1 cup flour
$1 / 2$ teaspoon salt
4 teaspoons baking powder
3 tablespoons sugar
1 egg
1 cup milk
$1 / 4$ cup shortening (soft) or vegetable oil
Mix together the dry ingredients. Beat together the egg,
milk and shortening/oil. Add the liquids to the dry ingredients Mix quickly by hand. Pour into greased $8 \times 8$ or $9 \times 9$ baking pan. Bake at 425 degrees for 20-25 minutes.
