Subtypes

CSE 331

University of Washington
What is subtyping?

- Sometimes **every B is an A**
  In a library database:
  - every book is a library holding
  - every CD is a library holding
- Subtyping expresses this
  **B is a subtype of A** means:
  "every object that satisfies interface B also satisfies interface A"

- Goal: code written using A's specification operates correctly even if given a B
Subtypes are substitutable

• Subtypes are **substitutable** for supertypes
  – Instances of subtype won't surprise client by failing to satisfy the supertype's specification
  – Instances of subtype won't surprise client by having more expectations than the supertype's specification

• We say that B is a **true subtype** of A if B has a stronger specification than A
  – This is **not** the same as a **Java subtype**
  – Java subtypes that are not true subtypes are **dangerous**
Subtyping and subclassing

• Substitution (subtype)
  – B is a subtype of A iff an object of B can masquerade as an object of B in any context

• Inheritance (subclass)
  – Abstract out repeated code
  – Enables incremental changes to classes

• Every subclass is a Java subtype
  – But not necessarily a true subtype
Suppose we run a web store with a class for Products...

class Product {
    private String title;
    private String description;
    private float price;
    public float getPrice() { return price; }
    public float getTax() { return getPrice() * 0.095f; }
    // ...
}

... and we need a class for Products that are on sale
Code copying is a bad way to add functionality

We would never dream of cutting and pasting like this:

class SaleProduct {
    private String title;
    private String description;
    private float price;
    private float factor;
    public float getPrice() { return price*factor; }
    public float getTax() { return getPrice() * 0.095f; }
    //...
}
Inheritance makes small extensions small

It’s much better to do this:

class SaleProduct extends Product {
    private float factor;
    public float getPrice() {
        return super.getPrice() * factor;
    }
}

Benefits of subclassing & inheritance

Don’t repeat unchanged fields and methods

In implementation
  Simpler maintenance: just fix bugs once

In specification
  Clients who understand the superclass specification need only study novel parts of the subclass

Modularity: can ignore private fields and methods of superclass (if properly defined)

Differences are not buried under mass of similarities

Ability to substitute new implementations
  Clients need not change their code to use new subclasses
Subclassing can be misused

Poor planning leads to muddled inheritance hierarchy
  Relationships may not match untutored intuition
If subclass is tightly coupled with superclass
  Can depend on implementation details of superclass
  Changes in superclass can break subclass
  “fragile base class problem”

Subtyping and implementation inheritance are orthogonal
  – Subclassing gives you both
  – Sometimes you want just one
Every square is a rectangle (elementary school)

```java
interface Rectangle {
    // effects: fits shape to given size; that is:
    // this.post.width = w, this.post.height = h
    void setSize(int w, int h);
}
```

Choose the best option for Square.setSize():

```java
// Interface 1
interface Square implements Rectangle {
    // requires: w = h
    // effects: fits shape to given size
    void setSize(int w, int h);
}

// Interface 2
interface Square implements Rectangle {
    // effects: sets all edges to given size
    void setSize(int edgeLength);
}

// Interface 3
interface Square implements Rectangle {
    // effects: fits shape to given size
    // throws BadSizeException if w != h
    void setSize(int w, int h)
        throws BadSizeException;
}
```
Square and rectangle are unrelated (Java)

Square is not a (true subtype of) Rectangle:
- Rectangles are expected to have a width and height that can be changed independently
- Squares violate that expectation, could surprise client

Rectangle is not a (true subtype of) Square:
- Squares are expected to have equal widths and heights
- Rectangles violate that expectation, could surprise client

Inheritance isn't always intuitive
- Benefit: it forces clear thinking and prevents errors

Solutions:
- Make them unrelated (or siblings under a common parent)
- Make them immutable
class Hashtable<K,V> {  
  // modifies: this  
  // effects: associates the specified value with the specified key  
  public void put (K key, V value);  

  // returns: value with which the  
  // specified key is associated  
  public V get (K key);  
}

class Properties extends Hashtable<Object,Object> {  // simplified  
  // modifies: this  
  // effects: associates the specified value with the specified key  
  public void setProperty (String key, String val) { put(key,val); }  

  // returns: the string with which the key is associated  
  public String getProperty (String key) { return (String) get(key); }  
}

Properties class stores string key-value pairs. It extends Hashtable functionality. What's the problem?

Inappropriate subtyping in the JDK

Properties tbl = new Properties();
tbl.put("One", new Integer(1));
tbl.getProperty("One"); // crash!
Violation of superclass specification

Properties class has a simple rep invariant:
   keys and values are Strings
But client can treat Properties as a Hashtable
   Can put in arbitrary content, break rep invariant

From Javadoc:
   Because Properties inherits from Hashtable, the put and putAll methods can be applied to a Properties object. ...
   If the store or save method is called on a "compromised" Properties object that contains a non-String key or value, the call will fail.

Also, the semantics are more confusing than I've shown
   getProperty("prop") works differently than get("prop")!
Solution 1: Generics

Bad choice:

```java
class Properties extends Hashtable<Object, Object> { ... }
```

Better choice:

```java
class Properties extends Hashtable<String, String> { ... }
```

Why didn’t the JDK designers make this choice?
Aside: subtyping for generics

Subtyping requires invariant generic types
A later lecture will explain why
Exception: super wildcard is a supertype of what it matches
Don’t use raw types like List! (CSE 331 forbids it)
Solution 2: Composition

class Properties {  // no "extends" clause!
    private Hashtable<Object, Object> hashtable;  // the "delegate"

    // requires: key and value are not null
    // modifies: this
    // effects: associates specified value with specified key
    public void setProperty (String key, String value) {
        hashtable.put(key,value);
    }

    // effects: returns string with which key is associated
    public String getProperty (String key) {
        return (String) hashtable.get(key);
    }
    ...
}
Substitution principle

• If B is a subtype of A, a B can always be substituted for an A

• Any property guaranteed by supertype must be guaranteed by subtype
  – The subtype is permitted to strengthen & add properties
  – Anything provable about an A is provable about a B
  – If instance of subtype is treated purely as supertype – only supertype methods and fields queried – then result should be consistent with an object of the supertype being manipulated

• No specification weakening
  – No method removal
  – An overriding method has
    • a weaker precondition
    • a stronger postcondition
Substitution principle

• Constraints on methods
  – For each method in supertype, subtype must have a corresponding overriding method
    • may also introduce new methods

• Each overriding method must:
  – Ask nothing extra of client ("weaker precondition")
    • Requires clause is at most as strict as in the supertype method
  – Guarantee at least as much ("stronger postcondition")
    • Effects clause is at least as strict as in the supertype method
    • No new entries in modifies clause
Substitution: spec weakening

• Method inputs:
  – Argument types may be replaced with supertypes ("contravariance")
  – This places no extra demand on the client
  – Java forbids any change (Why?)

• Method results:
  – Result type may be replaced with a subtype ("covariance")
    • This doesn't violate any expectation of the client
  – No new exceptions (for values in the domain)
  – Existing exceptions can be replaced with subtypes
    • This doesn't violate any expectation of the client
Substitution exercise

Suppose we have a method that, when given one product, recommends another:

```java
class Product {
    Product recommend(Product ref); }
```

Which of these are possible forms of method in `SaleProduct`?

```java
Product recommend(SaleProduct ref);       // bad
SaleProduct recommend(Product ref);       // OK
Product recommend(Object ref);            // OK, but is Java overloading
Product recommend(Product ref) throws NoSaleException;  // bad
```

Same kind of reasoning for exception subtyping, and modifies clause
JDK example: not a stronger spec

class HasTable {  // class is somewhat simplified (generics omitted)
   // modifies: this
   // effects: associates the specified value with the specified key
   public void put (Object key, Object value);  

   // returns: value with which the
   // specified key is associated
   public Object get (Object key);  
}

class Properties extends Hashtable {
   // modifies: this
   // effects: associates the specified value with the specified key
   public void put (String key, String val) { super.put(key,val); }  

   // returns: the string with which the key is associated
   public String get (String key) { return (String)super.get(key); }  
}
Is this good Inheritance?

Depends on the members, methods and the specifications
Java subtypes

- **Java types:**
  - Defined by classes, interfaces, primitives

- **B is Java subtype of A if:**
  - declared relationship (B extends A, B implements A)

- **Compiler checks, for each corresponding method:**
  - same argument types
  - compatible result types ("covariant return")
  - no additional declared exceptions
True subtypes versus Java subtypes

• Java requires type equality for parameters
  – Different types are treated as different methods
  – Stricter than needed, but simplifies syntax and semantics.
• Java permits covariant return type
  – A recent language feature, not reflected in (e.g.) `clone`
• Java has no notion of specification beyond method signatures
  – No check on precondition/postcondition
  – No check on promised properties (invariants)
Compiler guarantees about Java subtypes

• Objects are guaranteed to be (Java) subtypes of their declared type
  – If a variable of *declared (compile-time)* type T holds a reference to an object of *actual (runtime)* type T', then T' is a (Java) subtype of T

• Corollaries:
  – Objects always have implementations of the methods specified by their declared type
  – If all subtypes are true subtypes, then all objects meet the specification of their declared type

• Rules out a huge class of bugs
Inheritance breaks encapsulation

```java
public class InstrumentedHashSet<E> extends HashSet<E> {
    private int addCount = 0; // count attempted insertions
    public InstrumentedHashSet(Collection<? extends E> c) {
        super(c);
    }
    public boolean add(E o) {
        addCount++;
        return super.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();
        return super.addAll(c);
    }
    public int getAddCount() { return addCount; }
}
```
Dependence on implementation

What does this code print?

```java
InstrumentedHashSet<String> s =
    new InstrumentedHashSet<String>();
System.out.println(s.getAddCount()); // 0
s.addAll(Arrays.asList("CSE", "331");
System.out.println(s.getAddCount()); // 4!
```

• Answer depends on implementation of addAll() in HashSet
  – Different implementations may behave differently!
  – HashSet.addAll() calls add() ⇒ double-counting

• AbstractCollection.addAll specification states:
  – “Adds all of the elements in the specified collection to this collection.”
  – Does not specify whether it calls add()

• Lesson: designers should plan for their classes to be extended
Solutions

1. Change spec of HashSet
   Indicate all self-calls
   Less flexibility for implementers of specification

2. Eliminate spec ambiguity by avoiding self-calls
   a) “Re-implement” methods such as addAll
      Requires re-implementing methods
   b) Use a wrapper
      No longer a subtype (unless an interface is handy)
      Bad for callbacks, equality tests, etc.
public class InstrumentedHashSet<E> {
    private final HashSet<E> s = new HashSet<E>();
    private int addCount = 0;
    public InstrumentedHashSet(Collection<? extends E> c) {
        this.addAll(c);
    }
    public boolean add(E o) {
        addCount++;   return s.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();   return s.addAll(c);
    }
    public int getAddCount() {  return addCount; }
    // ... and every other method specified by HashSet<E>
}
Composition (wrappers, delegation)

- Implementation *reuse without inheritance*
- Easy to reason about; self-calls are irrelevant
- Example of a “wrapper” class
- Works around badly-designed classes
- Disadvantages (may be a worthwhile price to pay):
  - May be hard to apply to callbacks, equality tests
  - Tedious to write (your IDE will help you)
  - Does not preserve subtyping
Composition does not preserve subtyping

- InstrumentedHashSet is not a HashSet anymore
  - So can't easily substitute it
- It may be a true subtype of HashSet
  - But Java doesn't know that!
  - Java requires declared relationships
  - Not enough to just meet specification
- Interfaces to the rescue
  - Can declare that we implement interface Set
  - If such an interface exists
Interfaces reintroduce Java subtyping

```java
public class InstrumentedHashSet<E> implements Set<E> {
    private final Set<E> s = new HashSet<E>();
    private int addCount = 0;
    public InstrumentedHashSet(Collection<? extends E> c) {
        this.addAll(c);
    }
    public boolean add(E o) {
        addCount++;
        return s.add(o);
    }
    public boolean addAll(Collection<? extends E> c) {
        addCount += c.size();
        return s.addAll(c);
    }
    public int getAddCount() { return addCount; }
    // ... and every other method specified by Set<E>
}
```

What about this constructor?
```java
InstrumentedHashSet(Set<E> s) {
    this.s = s;
    addCount = s.size();
}
```
Interfaces and abstract classes

• Provide interfaces for your functionality
  – The client codes to interfaces rather than concrete classes
  – Allows different implementations later
  – Facilitates composition, wrapper classes
    • Basis of lots of useful, clever tricks
    • We'll see more of these later

• Consider providing helper/template abstract classes
  – Can minimize number of methods that new implementation must provide
  – Makes writing new implementations much easier
  – Using them is entirely optional, so they don't limit freedom to create radically different implementations
Why interfaces instead of classes

• Java design decisions:
  – A class has exactly one superclass
  – A class may implement multiple interfaces
  – An interface may extend multiple interfaces

• Observation:
  – multiple superclasses are difficult to use and to implement
  – multiple interfaces, single superclass gets most of the benefit
Pluses and minuses of inheritance

• Inheritance is a powerful way to achieve code reuse
• Inheritance can break encapsulation
  – A subclass may need to depend on unspecified details of the implementation of its superclass
    • e.g., pattern of self-calls
  – Subclass may need to evolve in tandem with superclass
    • Safe within a package where implementation of both is under control of same programmer
• Authors of superclass should design and document self-use, to simplify extension
  – Otherwise, avoid implementation inheritance and use composition instead

Type qualifiers

A way of using subtyping when you can’t write a new class

- Can express more than Java’s built-in type system

**Date** is a type

- [@Nullable Date] is a type
- [@NonNull Date] is a type

```java
Date d1; // 7/4/1776, 1/14/2011, null, ...
@Nullable Date d2; // same values as Date
@NonNull Date d3; // 7/4/1776, 1/14/2011, ...
```
Nullness subtyping relationship

- Which type hierarchy is best?

- A subtype has fewer values
- A subtype has more operations
- A subtype is substitutable
- A subtype preserves supertype properties
