CSE 331
Software Design & Implementation

Hal Perkins
Winter 2013
Usability
(Slides by Mike Ernst and David Notkin based on slides due to Robin Miller)
Usability

A lecture on usability won’t make anyone an interface expert – any more than using LaTeX makes one a graphics designer. But it’s important to have some appreciation for the issues. And you’re designing a UI in hw9….
A User Interface Example

Source: Interface Hall of Shame
What’s wrong?

- Usability is about creating effective user interfaces
- The first slide shows a WYSIWYG GUI – but it still fails – why?
- The long help message is needed for a simple task because the interface is bizarre!
  - The scrollbar is used to select an award template
  - Each position on the scrollbar represents a template, and moving the scrollbar back and forth changes the template shown
  - Cute but bad use of a scrollbar
  - How many templates? No indication on scrollbar
  - How are the templates organized? No hint
User Interface Hall of Shame

- Inconsistent with common usage of scrollbars – usually used for continuous scrolling, not discrete selection
- How does a frequent user find a template they’ve used before?
Redesigning the Interface

Source: Interface Hall of Shame
Another for the Hall of Shame

• The date and time *look* editable but aren’t – click “Set Time” for a dialog box instead
• Dialog box displays inconsistently with launch time – 12 vs. 24, analog vs. digital
• Click left [right] button to increase the minutes [hours] by 1 – makes a sophisticated GUI into a clock radio!
Hall of Fame or Hall of Shame?

Original Gimp windows had no menus – instead, right-click to get a popup menu and navigate further. Is this a fast way to select commands?
User Interfaces Are Hard to Design

• You are not the user
  – Most software engineering is about communicating with other programmers
  – UI is about communicating with users
• The user is always right
  – Consistent problems are the system’s fault
• …but the user is not always right
  – Users aren’t designers
Iterative Design

• UI development is an iterative process

  Design  

  Evaluate  Implement

• Iterations can be costly
  – If the design turns out to be bad, you may have to throw away most of your code
Spiral Model

- Use throw-away prototypes and cheap evaluation for early iterations
Usability Defined

- Usability: how well users can use the system’s functionality
- Dimensions of usability
  - Learnability: is it easy to learn?
  - Efficiency: once learned, is it fast to use?
  - Memorability: is it easy to remember what you learned?
  - Errors: are errors few and recoverable?
  - Satisfaction: is it enjoyable to use?
Lecture Outline

1. Design
   design principles

2. Implement
   low-fidelity prototypes

3. Evaluate
   user testing
Learnability

- Related to “intuitive” and “user-friendly”
- The first example had serious problems with learnability, especially with the scrollbar
  - Unfamiliar usage
  - Inconsistent usage
  - And outright inappropriate usage

Source: Interface Hall of Shame
Metaphorical Design

- Designers based it on a real-world plastic CD case
- Metaphors are one way to make an interface “intuitive,” since users can make guesses about how it will work
- Dominated by static artwork – clicking it does nothing
- Why? A CD case doesn’t actually play CDs, so the designers had to find a place for the core player controls
- The metaphor is dictating control layout, against all other considerations
- Also disregards consistency with other desktop applications. Close box? Shut it down?

Source: Interface Hall of Shame
People Don't Learn Instantly

- To design for learnability it helps to know how people actually learn
- This example shows overreliance on the user’s memory
  - It’s a modal dialog box, so the user needs to click OK
  - But then the instructions vanish from the screen, and the user is left to struggle to remember them
  - Just because you've said it, doesn't mean they know it

Source: Interface Hall of Shame
Some Facts About Memory & Learning

• Working memory
  – Small: 7 ± 2 “chunks”
  – Short-lived: gone in ~10 sec
  – Maintenance rehearsal is required to keep it from decaying (but costs attention)

• Long-term memory
  – Practically infinite in size and duration
  – Elaborative rehearsal transfers chunks to long-term memory
Design Principles for Learnability

- Consistency
  - Similar things look similar, different things different
  - Terminology, location, argument order, ...
  - Internal, external, metaphorical

- Match the real world
  - Common words, not tech jargon

- Recognition, not recall
  - Labeled buttons are better than command languages
  - Combo boxes are better than text boxes

Source: Interface Hall of Shame
Visibility

- Familiar, easy to use
- But passes up some tremendous opportunities, including
  - Why only one line of display?
  - Why not a history?
  - Why only one memory slot? Why display “M” instead of the actual number stored in memory?
  - Visibility also compromised by invisible modes
    - When entering a number, pressing a digit appends it to the number; but after pressing an operator button, the next digit starts a new number – no visible feedback the low-level mode
    - It also lets you type numbers on the keyboard, but there is no hint about this
Organizational Realignment

In order to meet our growing sales demands, and to optimize the supply chain throughout our worldwide operations, Fabrikam is pleased to announce the realignment of our sales and manufacturing workforce worldwide. The next executive leadership team outlined in the table below will streamline each of our regional operations to maximize profit in the way that best
Facts About Human Perception

• **Perceptual fusion**: stimuli < 100ms apart appear fused to our perceptual systems
  – 10 frames/sec is enough to perceive a moving picture
  – Computer response < 100 ms feels instantaneous

• **Color blindness**: many users (~8% of all males) can't distinguish red from green

![normal vision](image1.png) ![red-green deficient](image2.png)
Design Principles for Visibility

• Make system state visible: keep the user informed about what's going on
  – Mouse cursor, selection highlight, status bar

• Give prompt feedback
  – Response time rules-of-thumb
    < 0.1 sec  seems instantaneous
    0.1-1 sec  user notices, but no feedback needed
    1-5 sec   display busy cursor
    > 1-5 sec  display progress bar
Progress bars…

I'm just outside town, so I should be there in fifteen minutes.

Actually, it's looking more like six days.

No, wait, thirty seconds.

The author of the Windows file copy dialog visits some friends.
Efficiency

- How quickly can an expert operate the system – input, commands, perceiving and processing output
- About the performance of the I/O channel between the user and the program
- Fewer keystrokes to do a task is usually more efficient; but it’s subtle
- The old Gimp interface used only contextual, cascading submenus – studies show it’s actually slower to use than a menu bar
Some Facts About Motor Processing

- **Open-loop control**
  - Motor processor runs by itself
  - Cycle time is ~ 70 ms
- **Closed-loop control**
  - Muscle movements (or their effect on the world) are perceived and compared with desired result
  - Cycle time is ~ 240 ms
Pointing Tasks: Fitts’s Law

• How long does it take to reach a target?

  – Moving mouse to target on screen
  – Moving finger to key on keyboard
  – Moving hand between keyboard and mouse
Analytical Derivation of Fitts’s Law

• Moving your hand to a target is closed-loop control
• Each cycle covers remaining distance $D$ with error $\varepsilon D$
• After 2 cycles, within $\varepsilon^2 D$ of target
Fitts’ s Law

- $T = RT + MT = a + b \log (D/S)$

  - $\log(D/S)$ is the index of difficulty of the pointing task
Path Steering Tasks

• Fitts’ s Law applies only if path to target is unconstrained
• But the task is much harder if path is constrained to a tunnel

\[ T = a + b \left( \frac{D}{S} \right) \]

• This is why cascading menus are slow!
Design Principles for Efficiency

• Fitts's Law and Steering Law
  – Make important targets big, nearby, or at screen edges
  – Avoid steering tasks

• Provide shortcuts
  – Keyboard accelerators
  – Styles
  – Bookmarks
  – History
Mode Error

• Modes: states in which actions have different meanings
  – Vi’s insert mode vs. command mode
  – Drawing palette

• Avoiding mode errors
  – Eliminate modes entirely
  – Visibility of mode
  – Spring-loaded or temporary modes
  – Disjoint action sets in different modes
Confirmation Dialogs
Confirmation Dialogs: “Are you sure?”

- They make common operations take two button presses rather than one.
- Frequent confirmations dialogs lead to expert users chunking it as part of the operation.
- Reversibility (i.e. undo) is a far better solution than confirmation – operations that are very hard to reverse may deserve confirmation, however.
Design Principles for Error Handling

• Prevent errors as much as possible
  – Selection is better than typing
  – Avoid mode errors
  – Disable illegal commands
  – Separate risky commands from common ones
• Use confirmation dialogs sparingly
• Support undo
• Good error messages
  – Precise
  – Speak the user’s language
  – Constructive help
  – Polite

Source: Interface Hall of Shame
Simplicity

Source: Alex Papadimoulis
Design Principles for Simplicity

• “Less is More”
  – Omit extraneous information, graphics, features

• Good graphic design
  – Few, well-chosen colors and fonts
  – Group with whitespace

• Use concise language
  – Choose labels carefully
Document your system

- Write the user manual
  - Program and UI metaphors
  - Key functionality
  - Not: exhaustive list of all menus
- What is hard to describe?
- Who is your target user?
  - Power users need a manual
  - Casual users might not
  - Piecemeal online help is no substitute
Lecture Outline

1. Design
   design principles

2. Implement
   low-fidelity prototypes

3. Evaluate
   user testing
Low-fidelity Prototypes

• Paper is a very fast and effective prototyping tool
  – Sketch windows, menus, dialogs, widgets
  – Crank out lots of designs and evaluate them

• Hand-sketching is OK – even preferable
  – Focus on behavior & interaction, not fonts & colors
  – Similar to design of your data structures & algorithms

• Paper prototypes can even be executed
  – Use pieces to represent windows, dialogs, menus
  – Simulate the computer’s responses by moving pieces around and writing on them
Paper Prototypes
Paper Prototypes
Paper Prototypes
User Testing

• Start with a prototype
• Write up a few representative tasks
  – Short, but not trivial
  – e.g.:  “add this meeting to calendar”,
         “type this letter and print it”
• Find a few representative users
  – 3 is often enough to find obvious problems
• Watch them do tasks with the prototype
How to Watch Users

• Brief the user first (being a test user is stressful)
  – “I’m testing the system, not testing you”
  – “If you have trouble, it’s the system’s fault”
  – “Feel free to quit at any time”
  – Ethical issues: informed consent

• Ask user to think aloud

• Be quiet!
  – Don’t help, don’t explain, don’t point out mistakes
  – Sit on your hands if it helps
  – Two exceptions: prod user to think aloud (“what are you thinking now?”), and move on to next task when stuck

• Take lots of notes
Watch for Critical Incidents

- Critical incidents: events that strongly affect task performance or satisfaction
- Usually negative
  - Errors
  - Repeated attempts
  - Curses
- Can also be positive
  - “Cool!”
  - “Oh, now I see.”
You are not the user
Keep human capabilities and design principles in mind
Iterate over your design
Write documentation
Make cheap, throw-away prototypes
Evaluate them with users
