CSE 331
Software Design & Implementation

Dan Grossman
Fall 2014
System Integration and Software Process
(Based on slides by Mike Emst, David Notkin, Hal Perkins)

Context

CSE331 is almost over… 😊

- Focus on software design, specification, testing, and implementation
  - Absolutely necessary stuff for any nontrivial project
- But not sufficient for the real world: At least 2 key missing pieces
  - Techniques for larger systems and development teams
    - This lecture; yes fair game for final exam
    - Major focus of CSE403
  - Usability: interfaces engineered for humans
    - The lecture we missed when Nov 21 was cancelled
    - Major focus of CSE440

Outline

- Software architecture
- Tools
  - For build management
  - For version control
  - For bug tracking
- Scheduling
- Implementation and testing order

Architecture

Software architecture refers to the high-level structure of a software system

- A principled approach to partitioning the modules and controlling dependencies and data flow among the modules

Common architectures have well-known names and well-known advantages/disadvantages

A good architecture ensures:
- Work can proceed in parallel
- Progress can be closely monitored
- The parts combine to provide the desired functionality

Example architectures

Pipe-and-filter (think: iterators)

Layered (think: levels of abstraction)

Blackboard (think: callbacks)

A good architecture allows:

- Scaling to support large numbers of ______
- Adding and changing features
- Integration of acquired components
- Communication with other software
- Easy customization
  - Ideally with no programming
  - Turning users into programmers is good
- Software to be embedded within a larger system
- Recovery from wrong decisions
  - About technology
  - About markets
System architecture

• Have one!
• Subject it to serious scrutiny
  – At relatively high level of abstraction
  – Basically lays down communication protocols
• Strive for simplicity
  – Flat is good
  – Know when to say no
  – A good architecture rules things out
• Reusable components should be a design goal
  – Software is capital
  – This will not happen by accident
  – May compete with other goals the organization behind the project has (but less so in the global view and long-term)

Temptations to avoid

• Avoid featureitis
  – Costs under-estimated
  – Effects of scale discounted
  – Benefits over-estimated
  – A Swiss Army knife is rarely the right tool
• Avoid digressions
  – Infrastructure
  – Premature tuning
  – Often addresses the wrong problem
• Avoid quantum leaps
  – Occasionally, great leaps forward
  – More often, into the abyss

Outline

• Software architecture
• Tools
  – For build management
  – For version control
  – For bug tracking
• Scheduling
• Implementation and testing order

Build tools

• Building software requires many tools:
  – Java compiler, C/C++ compiler, GUI builder, Device driver build tool, InstallShield, Web server, Database, scripting language for build automation, parser generator, test generator, test harness
• Reproducibility is essential
• System may run on multiple devices
  – Each has its own build tools
• Everyone needs to have the same toolset!
  – Wrong or missing tool can drastically reduce productivity
• Hard to switch tools in mid-project

Version control (source code control)

• A version control system lets you:
  – Collect work (code, documents) from all team members
  – Synchronize team members to current source
  – Have multiple teams make progress in parallel
  – Manage multiple versions, releases of the software
  – Identify regressions more easily
• Example tools:
  – Subversion (SVN), Mercurial (Hg), Git
• Policies are even more important
  – When to check in, when to update, when to branch and merge, how builds are done
  – Policies need to change to match the state of the project
• Always diff before you commit

Bug tracking

• An issue tracking system supports:
  – Tracking and fixing bugs
  – Identifying problem areas and managing them
  – Communicating among team members
  – Tracking regressions and repeated bugs
• Essential for any non-small or non-short project
• Example tools:
  – Bugzilla, Flyspray, Trac, hosted tools (Sourceforge, Google Developers, GitHub, Bitbucket, …)

If you’re doing work the computer could do for you, then you’re probably doing it wrong
Bug tracking

Need to configure the bug tracking system to match the project
- Many configurations can be too complex to be useful
A good process is key to managing bugs
- An explicit policy that everyone knows, follows, and believes in

Outline

- Software architecture
- Tools
  - For build management
  - For version control
  - For bug tracking
- Scheduling
- Implementation and testing order

Scheduling

“More software projects have gone awry for lack of calendar time
than for all other causes combined.”
-- Fred Brooks, The Mythical Man-Month

Three central questions of the software business
3. When will it be done?
2. How much will it cost?
1. When will it be done?

- Estimates are almost always too optimistic
- Estimates reflect what one wishes to be true
- We confuse effort with progress
- Progress is poorly monitored
- Slippage is not aggressively treated

Scheduling is crucial but underappreciated

- Scheduling is underappreciated
  - Made to fit other constraints
- A schedule is needed to make slippage visible
  - Must be objectively checkable by outsiders
- Unrealistically optimistic schedules are a disaster
  - Decisions get made at the wrong time
  - Decisions get made by the wrong people
  - Decisions get made for the wrong reasons
- The great paradox of scheduling:
  - Hofstadter’s Law: It always takes longer than you expect,
    even when you take into account Hofstadter’s Law
  - But seriously: 2x longer, even if think it will take 2x longer

Effort is not the same as progress

Cost is the product of workers and time
- Reasonable approximation: All non-people costs (mostly salary) are zero (?!)
- Easy to track

Progress is more complicated
- Hard to track

- People don’t like to admit lack of progress
  - Think they can catch up before anyone notices
  - Assume they (you) are wrong
- Design the process and architecture to facilitate tracking

How does a project get to be one year late?

One day at a time…
- It’s not the hurricanes that get you
- It’s the termites
  - Tom missed a meeting
  - Mary’s keyboard broke
  - The compiler wasn’t updated
  - …

If you find yourself ahead of schedule
- Don’t relax
- Don’t add features
Controlling the schedule

• First, you must have one
• Avoid non-verifiable milestones
  – 90% of coding done
  – 90% of debugging done
  – Design complete
• 100% events are verifiable milestones
  – Module 100% coded
  – Unit testing successfully complete
• Need critical path chart (Gantt chart, PERT chart)
  – Know effects of slippage
  – Know what to work on when

Milestones

• Milestones are critical keep the project on track
  – Policies may change at major milestones
  – Check-in rules, build process, etc.
• Some typical milestones (names)
  – Design complete
  – Interfaces complete / feature complete
  – Code complete / code freeze
  – Alpha release
  – Beta release
  – Release candidate (RC)
  – FCS (First Commercial Shipment) release

Dealing with slippage

• People must be held accountable
  – Slippage is not inevitable
  – Software should be on time, on budget, and on function
• Four options
  – Add people – startup cost (“mythical man-month”)
  – Buy components – hard in mid-stream
  – Change deliverables – customer must approve
  – Change schedule – customer must approve
• Take no small slips
  – One big adjustment is better than three small ones

Outline

• Software architecture
• Tools
  – For build management
  – For version control
  – For bug tracking
• Scheduling
• Implementation and testing order

How to code and test your design

• You have a design and architecture
  – Need to code and test the system
• Key question, what to do when?
• Suppose the system has this module dependency diagram
  – In what order should you address the pieces?

Bottom-up

• Implement/test children first
  – For example: G, E, B, F, C, D, A
• First, test G stand-alone (also E)
  – Generate test data as discussed earlier
  – Construct drivers
• Next, implement/test B, F, C, D
• No longer unit testing: use lower-level modules
  – A test of module M tests:
    • whether M works, and
    • whether modules M calls behave as expected
  – When a failure occurs, many possible sources of defect
  – Integration testing is hard, irrespective of order
Building drivers

- Use a person
  - *Simplest* choice, but also *worst* choice
  - Errors in entering data are inevitable
  - Errors in checking results are inevitable
  - Tests are not easily reproducible
    - Problem for debugging
    - Problem for regression testing
  - Test sets stay small, don’t grow over time
  - Testing cannot be done as a background task
- Better alternative: Automated drivers in a test harness

Top-down

- Implement/test parents (clients) first
  - Here, we start with A
- To run A, build *stubs* to simulate B, C, and D
- Next, choose a successor module, e.g., B
  - Build a stub for E
  - Drive B using A
- Suppose C is next
  - Can we reuse the stub for E?

Implementing a stub

- Query a person at a console
  - Same drawbacks as using a person as a driver
- Print a message describing the call
  - Name of procedure and arguments
  - Fine if calling program does not need result
    - More common than you might think
- Provide “canned” or generated sequence of results
  - Often sufficient
  - Generate using criteria used to generate data for unit test
  - May need different stubs for different callers
- Provide a primitive (inefficient & incomplete) implementation
  - Best choice, if not too much work
  - Look-up table often works
  - Sometimes called “mock objects” (ignoring technical definitions?)

Comparing top-down and bottom-up

- Criteria
  - What kinds of errors are caught when?
  - How much integration is done at a time?
  - Distribution of testing time?
  - Amount of work?
  - What is working when (during the process)?
- Neither dominates
  - Useful to understand advantages/disadvantages of each
  - Helps you to design an appropriate mixed strategy

Catching design errors

- Top-down tests global decisions first
  - E.g., what system does
  - Most devastating place to be wrong
  - Good to find early
- Bottom-up uncovers efficiency problems earlier
  - Constraints often propagate downward
  - You may discover they can’t be met at lower levels

What components work, when?

- Bottom-up involves lots of invisible activity
  - 90% of code written and debugged
  - Yet little that can be demonstrated
- Top-down depth-first
  - Earlier completion of useful partial versions
Amount of integration at each step

- Less is better
- Top-down adds one module at a time
  - When an error is detected, either:
    - Lower-level module doesn't meet specification
    - Higher-level module tested with bad stub
- Bottom-up adds one module at a time
  - Connect it to multiple modules
  - Thus integrating more modules at each step
  - More places to look for error

Amount of work

- Always need test harness
- Top-down
  - Build stubs but not drivers
- Bottom-up
  - Build drivers but not stubs
- Stubs are usually more work than drivers
  - Particularly true for data abstractions
- On average, top-down requires more non-deliverable code
  - Not necessarily bad

Distribution of testing time

- Integration is what takes the time
- Bottom-up gets harder as you proceed
  - You may have tested 90% of code
    - But you still have far more than 10% of the work left
  - Makes prediction difficult
- Top-down more evenly distributed
  - Better predictions
  - Uses more machine time (could be an issue)
    - Because testing overall (even if stubbed) functionality

One good way to structure an implementation

- Largely top-down
  - But always unit test modules
- Bottom-up
  - When stubs are too much work [just implement real thing]
  - Low level module that is used in lots of places
  - Low-level performance concerns
- Depth-first, visible-first
  - Allows interaction with customers, like prototyping
  - Lowers risk of having nothing useful
  - Improves morale of customers and programmers
    - Needn’t explain how much invisible work done
    - Better understanding of where the project is
    - Don’t have integration hanging over your head

Test harnesses

- Goals:
  - Increase amount of testing over time
  - Facilitate regression testing
  - Reduce human time spent on testing
- Take input from a file
- Call module being tested
- Save results (if possible)
  - Including performance information
- Check results
  - At best, is correct
  - At worst, same as last time
- Generate reports

Regression testing

- Ensure that things that used to work still do
  - Including performance
  - Whenever a change is made
- Knowing exactly when a bug is introduced is important
  - Keep old test results
  - Keep versions of code that match those results
  - Storage is cheap
