Announcements

• Readability reviews
  – ungraded feedback in src/hw6/readability.md
  – added details on what I will look for in graded reviews
    (see the documents page on the web site)

• Quiz #5 due by 11pm.
• Quiz #6 will be posted Saturday.

• HW #7
  – benefit from already having tests for HW5 & HW6
Review: Module Design

• Want cohesion within a single module
  – lack of cohesion suggests it could be split

• Do not want coupling between modules
  – makes each difficult to build & reason about independently
  – makes bugs more likely
  – makes each module more difficult to change

• Example: superclass and subclass are often tightly coupled
  – unseen dependencies such as patterns of “self calls”
  – EJ: prefer composition

• Today: design examples and one pattern to improve designs
Design exercise #1

Write a typing-break reminder program

Offer the hard-working user occasional reminders of the perils of Repetitive Strain Injury, and encourage the user to take a break from typing.

Naive design:

– Make a method to display messages and offer exercises
– Make a loop to call that method from time to time
public class TimeToStretch {
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }
    public void suggestExercise() {
        ...
    }
}
Timer calls run() periodically

```java
public class Timer {
    private TimeToStretch tts = new TimeToStretch();
    public void start() {
        while (true) {
            ...
            if (enoughTimeHasPassed) {
                tts.run();
            }
            ...
        }
    }
}
```
Main class puts it together

class Main {
    public static void main(String[] args) {
        Timer t = new Timer();
        t.start();
    }
}

This program, as designed, will work...
    But we can do better
Module dependency diagram (MDD)

An arrow in a module dependency diagram (MDD) indicates “depends on” or “knows about”
- simplistically: “any name mentioned in the source code”

What’s wrong with this diagram?
- does Timer really need to depend on TimeToStretch?
- is Timer re-usable in a new context?
Decoupling

**Timer** needs to call the **run** method
- **Timer** does *not* need to know what the **run** method does

Weaken the dependency of **Timer** on **TimeToStretch**
- introduce a *weak* specification for what **Timer** needs

```java
public abstract class TimerTask {
    public abstract void run();
}
```

**Timer** only needs to know that something (e.g., **TimeToStretch**) meets the **TimerTask** specification
public class TimeToStretch extends TimerTask {
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }

    public void suggestExercise() {
        ... 
    }
}
public class Timer {
    private TimerTask task;
    public Timer(TimerTask task) {
        this.task = task;
    }
    public void start() {
        while (true) {
            ...  
            task.run();
        }
    }
}

Main creates a TimeToStretch object and passes it to Timer:

    Timer t = new Timer(new TimeToStretch());
    t.start();
Module dependency diagram (version 2)

- **Timer** depends on **TimerTask**, not **TimeToStretche**
  - unaffected by implementation details of **TimeToStretch**
  - now **Timer** is much easier to reuse
  - **Main** depends on the constructor for **TimeToStretch**
- **Main** still depends on **Timer** (is this necessary?)
The callback design pattern

An alternative: use a callback to invert the dependency

`TimeToStretch` creates a `Timer`, and passes in a reference to *itself* so the `Timer` can *call it back*

- this is a *callback*
- call from module to a client that it notifies about some condition

The callback *inverts a dependency*

- inverted dependency: `TimeToStretch` depends on `Timer` (not vice versa)
  - less obvious coding style, but more “natural” dependency
- side benefit: `Main` does not depend on `Timer`
Callbacks

Callback: “code” provided by client to be used by library
  • in Java, pass an object with the “code” in a method

*Synchronous* callbacks:
  • useful when library needs the callback result immediately
  • examples: `HashMap` calls its client’s `hashCode`, `equals`

*Asynchronous* callbacks:
  • `register` to indicate interest and where to call back
  • examples: GUI events, timers
  • useful when the callback should be performed later
    (when some interesting event occurs)
public class TimeToStretch extends TimerTask {
    private Timer timer;
    public TimeToStretch() {
        timer = new Timer(this);
    }
    public void start() {
        timer.start();
    }
    public void run() {
        System.out.println("Stop typing!");
        suggestExercise();
    }
    ...
}
Main (version 3)

TimeToStretch \texttt{tts} = \texttt{new TimeToStretch();}
\texttt{tts.start();}

- uses a callback in \texttt{TimeToStretch} to invert a dependency
- this MDD shows the inversion of the dependency between \texttt{Timer} and \texttt{TimeToStretch} (compare to version 1)
Decoupling and design

• Good design has dependences (coupling) only where sensible

• While you design (before you code), examine dependences
  – don’t introduce unnecessary coupling!

• Coupling is an easy temptation if you code first
  – suppose a method needs information from another object:
  – if you hack in a way to get it:
    • will damage the code’s modularity and reusability
    • more complex code is harder to understand
Design exercise #2

A program to display information about stocks
- stock tickers
- spreadsheets
- graphs

Naive design:
- make a class to represent stock information
- that class updates all views of that information (tickers, graphs, etc.) when it changes
Main class gathers information and stores in **Stocks**
- **Stocks** class updates viewers when necessary

Problem: To add/change a viewer, must change **Stocks**
Better: insulate **Stocks** from the vagaries of the viewers
Weaken the coupling

What should `Stocks` class know about viewers?
  - only needs an `update` method to call with changed data
  - old way:

```java
void updateViewers() {
    ticker.update(newPrice);
    spreadsheet.update(newPrice);
    graph.update(newPrice);
    // Edit this method to
    // add a new viewer. 😞
}
```
Weaken the coupling

What should Stocks class know about viewers?
- only needs an update method to call with changed data
- new way: The “observer pattern”

```java
interface PriceObserver {
    void update(PriceInfo pi);
}

class Stocks {
    private List<PriceObserver> observers;
    void addObserver(PriceObserver pi) {
        observers.add(pi);
    }
    void notifyObserver(PriceInfo i) {
        for (PriceObserver obs : observers)
            obs.update(i);
    }
    ...
}
```
The observer pattern

- **Stocks** not responsible for viewer creation
- **Main** passes viewers to **Stocks** as **observers**
- **Stocks** keeps list of **PriceObservers**, notifies them of changes

- **Issue**: **update** method must pass enough information to (unknown) viewers
A different design: pull versus push

- The Observer pattern implements push functionality
- A pull model: give viewers access to Stocks, let them extract the data they need

“Push” versus “pull” efficiency can depend on frequency of operations
(Also possible to use both patterns simultaneously.)
Another example of Observer pattern

// Represents a sign-up sheet of students
public class SignupSheet extends Observable {
    private List<String> students
        = new ArrayList<String>();
    public void addStudent(String student) {
        students.add(student);
        setChanged();
        notifyObservers();
    }
    public int size() {
        return students.size();
    }
}

SignupSheet inherits many methods including:
void addObserver(Observer o)
protected void setChanged()
void notifyObservers()
public class SignupObserver implements Observer {
    // called whenever observed object changes
    // and observers are notified
    public void update(Observable o, Object arg) {
        System.out.println("Signup count: "+((SignupSheet)o).size());
    }
}

Part of the JDK
Not relevant to us
cast because Observable is not generic 😞
Registering an observer

```java
SignupSheet s = new SignupSheet();
s.addStudent("billg");
// nothing visible happens
s.addObserver(new SignupObserver());
s.addStudent("torvalds");
// now text appears: "Signup count: 2"
```

Java's “Listeners” (particularly in GUI classes) are examples of the Observer pattern

(Feel free to use the Java observer classes in your designs – if they are a good fit – but you don’t have to use them)
User interfaces: appearance vs. content

It is easy to tangle up appearance and content
- especially when supporting direct manipulation (e.g., dragging line endpoints in a drawing program)
- example: program state stored in widgets in dialog boxes

Neither can be understood easily or changed easily

This destroys modularity and reusability
- Over time, it leads to bizarre hacks and huge complexity
- Code must be discarded

Callbacks, listeners, and other patterns can help
Advice

• Worry about dependencies
  – they make code hard to change

• But also worry about simplicity
  – sometimes the cure is worse than the disease
  – don’t introduce lots of new concepts and abstraction in order to fix what is not really a problem
  – Example: what if ticker, spreadsheet, and graph are the only observers we ever need?
