

CSE332: Data Abstractions

Lecture 5: Binary Heaps, Continued

Dan Grossman Spring 2010

Review

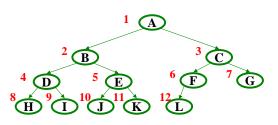

- Priority Queue ADT: insert comparable object, deleteMin
- Binary heap data structure: Complete binary tree where each node has priority value greater than its parent
- O(height-of-tree)=O(log n) insert and deleteMin operations
 - insert: put at new last position in tree and percolate-up
 - deleteMin: remove root, put last element at root and percolate-down
- But: tracking the "last position" is painful and we can do better

Spring 2010 CSE332: Data Abstractions 2

Array Representation of Binary Trees

From node i:

left child: i*2 right child: i*2+1 parent: i/2

(wasting index 0 is convenient)

implicit (array) implementation:

	A	В	C	D	E	F	G	Н	I	J	K	L	
0	1	2	3	4	5	6	7	8	9	10	11	12	13

Judging the array implementation

Plusses:

- Non-data space: just index 0 and unused space on right
 - In conventional tree representation, one edge per node (except for root), so n-1 wasted space (like linked lists)
 - Array would waste more space if tree were not complete
- For reasons you learn in CSE351 / CSE378, multiplying and dividing by 2 is very fast
- Last used position is just index size

Minuses:

• Same might-by-empty or might-get-full problems we saw with stacks and queues (resize by doubling as necessary)

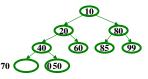

Plusses outweigh minuses: "this is how people do it"

4/14/2010 3 Spring 2010 CSE332: Data Abstractions 4

Pseudocode: insert

Note this pseudocode inserts ints, not useful data with priorities

```
void insert(int val) {
  if(size==arr.length-1)
    resize();
  size++;
  i=percolateUp(size,val);
  arr[i] = val;
}
int percolateUp(int hole,
    int val) {
  while(hole > 1 &&
    val < arr[hole/2])
    arr[hole] = arr[hole/2];
  hole = hole / 2;
  }
  return hole;
}</pre>
```

Pseudocode: deleteMin

Note this pseudocode deletes ints, not useful data with priorities

10

11

12

13

```
int percolateDown(int hole,
int deleteMin() {
                                                  int val) {
  if(isEmpty()) throw...
                               while(2*hole <= size) {</pre>
  ans = arr[1];
                                left = 2*hole;
 hole = percolateDown
                                right = left + 1;
                                if(arr[left] < arr[right]</pre>
          (1,arr[size]);
                                    | right > size)
  arr[hole] = arr[size];
                                  target = left;
  size--;
                                  target = right;
  return ans;
                                if(arr[target] < val) {</pre>
                                  arr[hole] = arr[target];
                                  hole = target;
                                } else
                                    break;
                               return hole;
             80
                  40
                      60
                          85
                               99
                                   700
                                        50
```

5

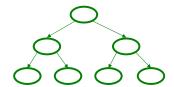

6

CSE332: Data Abstractions

Example

- 1. insert: 16, 32, 4, 69, 105, 43, 2
- 2. deleteMin

Other operations

Spring 2010

- decreaseKey: given pointer to object in priority queue (e.g., its array index), lower its priority value by p
 - Change priority and percolate up
- increaseKey: given pointer to object in priority queue (e.g., its array index), raise its priority value by p
 - Change priority and percolate down
- remove: given pointer to object, take it out of the queue
 - decreaseKey with $p = \infty$, then deleteMin

Running time for all these operations?

Spring 2010 CSE332: Data Abstractions 7 Spring 2010 CSE332: Data Abstractions 8

Build Heap

- Suppose you started with *n* items to put in a new priority queue
 - Call this the buildHeap operation
- create, followed by *n* inserts works
 - Only choice if ADT doesn't provide buildHeap explicitly
 - $-O(n \log n)$
- Why would an ADT provide this unnecessary operation?
 - Convenience
 - Efficiency: an O(n) algorithm called Floyd's Method
 - Common issue in ADT design: how many specialized operations

Spring 2010

CSE332: Data Abstractions

9

Floyd's Method

- 1. Use *n* items to make any complete tree you want
 - That is, put them in array indices 1,...,n
- 2. Treat it as a heap by fixing the heap-order property
 - Bottom-up: leaves are already in heap order, work up toward the root one level at a time

```
void buildHeap() {
  for(i = size/2; i>0; i--) {
    val = arr[i];
    hole = percolateDown(i,val);
    arr[hole] = val;
  }
}
```

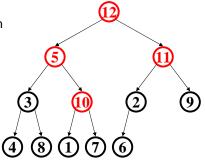

Spring 2010

CSE332: Data Abstractions

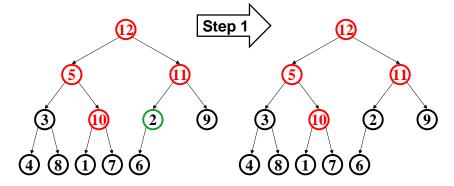

10

Example

- In tree form for readability
 - Red for node not less than descendants
 - heap-order problem
 - Notice no leaves are red
 - Check/fix each non-leaf bottom-up (6 steps here)

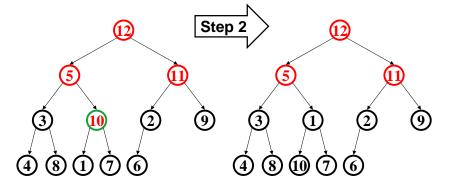

Example

• Happens to already be less than children (er, child)

Spring 2010 CSE332: Data Abstractions 11 Spring 2010 CSE332: Data Abstractions 12

Example

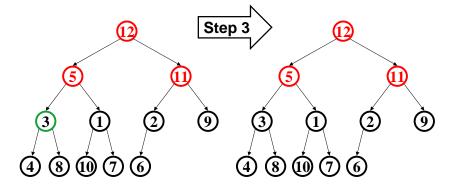

• Percolate down (notice that moves 1 up)

Spring 2010

CSE332: Data Abstractions

13

Example

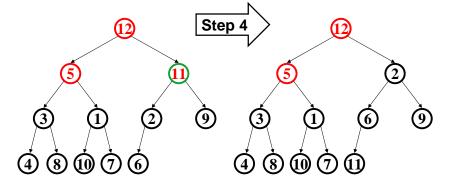

• Another nothing-to-do step

Spring 2010

CSE332: Data Abstractions

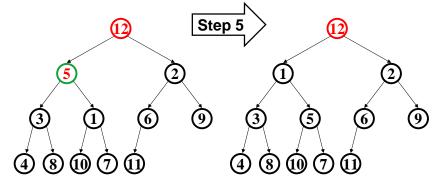

14

Example

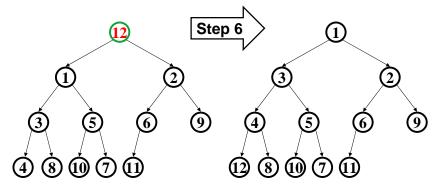

• Percolate down as necessary (steps 4a and 4b)

Example

Spring 2010 CSE332: Data Abstractions 15 Spring 2010 CSE332: Data Abstractions 16

Example

Spring 2010 CSE332: Data Abstractions

Correctness

```
void buildHeap() {
  for(i = size/2; i>0; i--) {
    val = arr[i];
    hole = percolateDown(i,val);
    arr[hole] = val;
  }
}
```

Loop Invariant: For all j>i, arr[j] is less than its children

- True initially: If j > size/2, then j is a leaf
 - Otherwise its left child would be at position > size
- True after one more iteration: loop body and percolateDown make arr[i] less than children without breaking the property for any descendants

So after the loop finishes, all nodes are less than their children

But is it right?

- "Seems to work"
 - Let's prove it restores the heap property (correctness)
 - Then let's prove its running time (efficiency)

```
void buildHeap() {
  for(i = size/2; i>0; i--) {
    val = arr[i];
    hole = percolateDown(i,val);
    arr[hole] = val;
  }
}
```

Spring 2010 CSE332: Data Abstractions 18

Efficiency

```
void buildHeap() {
  for(i = size/2; i>0; i--) {
    val = arr[i];
    hole = percolateDown(i,val);
    arr[hole] = val;
  }
}
```

Easy argument: buildHeap is $O(n \log n)$ where n is size

- size/2 loop iterations
- Each iteration does one percolateDown, each is $O(\log n)$

This is correct, but there is a more precise ("tighter") analysis of the algorithm...

Spring 2010 CSE332: Data Abstractions 19 Spring 2010 CSE332: Data Abstractions 20

17

Efficiency

```
void buildHeap() {
  for(i = size/2; i>0; i--) {
    val = arr[i];
    hole = percolateDown(i,val);
    arr[hole] = val;
  }
}
```

Better argument: buildHeap is O(n) where n is size

- size/2 total loop iterations: O(n)
- 1/2 the loop iterations percolate at most 1 step
- 1/4 the loop iterations percolate at most 2 steps
- 1/8 the loop iterations percolate at most 3 steps
- .
- ((1/2) + (2/4) + (3/8) + (4/16) + (5/32) + ...) < 2 (page 4 of Weiss)
 - So at most 2(size/2) total percolate steps: O(n)

Spring 2010 CSE332: Data Abstractions 21

What we're skipping (see text if curious)

- d-heaps: have d children instead of 2
 - Makes heaps shallower, useful for heaps too big for memory
 - The same issue arises for balanced binary search trees and we will study "B-Trees"
- Different data structures for priority queues that support a logarithmic time merge operation (impossible with binary heaps)
 - merge: given two priority queues, make one priority queue
 - How might you merge binary heaps:
 - If one heap is much smaller than the other?
 - If both are about the same size?

Lessons from buildHeap

- Without buildHeap, our ADT already let clients implement their own in θ(n log n) worst case
 - Worst case is inserting lower priority values later
- By providing a specialized operation internally (with access to the data structure), we can do O(n) worst case
 - Intuition: Most data is near a leaf, so better to percolate down
- Can analyze this algorithm for:
 - Correctness: Non-trivial inductive proof using loop invariant
 - Efficiency:
 - First analysis easily proved it was O(n log n)
 - A "tighter" analysis shows same algorithm is O(n)
