CSE 332: Data Abstractions
Lecture 19: Parallel Prefix, Pack, and Sorting

Ruth Anderson
Autumn 2013
Outline

Done:
- Simple ways to use parallelism for counting, summing, finding
- Analysis of running time and implications of Amdahl’s Law

Now: Clever ways to parallelize more than is intuitively possible
- Parallel prefix:
  - This “key trick” typically underlies surprising parallelization
  - Enables other things like packs (aka filters)
- Parallel sorting: quicksort (not in place) and mergesort
  - Easy to get a little parallelism
  - With cleverness can get a lot
The prefix-sum problem

Given int[] input, produce int[] output where:

\[ output[i] = input[0] + input[1] + \ldots + input[i] \]

| input | 6 | 4 | 16 | 10 | 16 | 14 | 2 | 8 |
| output | 6 | 10 | 26 | 36 | 52 | 66 | 68 | 76 |

Sequential can be a CSE142 exam problem:

```java
int[] prefix_sum(int[] input){
    int[] output = new int[input.length];
    output[0] = input[0];
    for(int i=1; i < input.length; i++)
        output[i] = output[i-1]+input[i];
    return output;
}
```

Does not seem parallelizable

- Work: \( O(n) \), Span: \( O(n) \)
- This algorithm is sequential, but a different algorithm has Work: \( O(n) \), Span: \( O(\log n) \)
Parallel prefix-sum

- The parallel-prefix algorithm does two passes
  - Each pass has $O(n)$ work and $O(\log n)$ span
  - So in total there is $O(n)$ work and $O(\log n)$ span
  - So like with array summing, parallelism is $n/\log n$
    - An exponential speedup

- First pass builds a tree bottom-up: the “up” pass

- Second pass traverses the tree top-down: the “down” pass
Local bragging

Historical note:
- Original algorithm due to R. Ladner and M. Fischer at UW in 1977
- Richard Ladner joined the UW faculty in 1971 and hasn’t left

1968? 1973? recent
Parallel Prefix: The Up Pass

We build want to **build a binary tree** where

- Root has sum of the range \([x,y)\)
- If a node has sum of \([lo,hi)\) and hi>lo,
  - Left child has sum of \([lo,middle)\)
  - Right child has sum of \([middle,hi)\)
  - A leaf has sum of \([i,i+1)\), which is simply input\(i\)

It is critical that we actually **create the tree** as we will need it for the down pass

- We do not need an actual linked structure
- We could use an array as we did with heaps

**Analysis of first step:** Work = Span =
The algorithm, part 1

Specifically.....

1. Propagate ‘sum’ up: Build a binary tree where
   – Root has sum of \text{input}[0]..\text{input}[n-1]
   – Each node has sum of \text{input}[lo]..\text{input}[hi-1]
     • Build up from leaves; parent.sum=left.sum+right.sum
   – A leaf’s sum is just it’s value; \text{input}[i]

This is an easy fork-join computation: combine results by actually building a binary tree with all the sums of ranges
   – Tree built bottom-up in parallel
   – Could be more clever; ex. Use an array as tree representation like we did for heaps

Analysis of first step: \( O(n) \) work, \( O(\log n) \) span
The (completely non-obvious) idea:
Do an initial pass to gather
information, enabling us to do a
second pass to get the answer

First we’ll gather
the ‘sum’ for each
recursive block

<table>
<thead>
<tr>
<th>input</th>
<th>6</th>
<th>4</th>
<th>16</th>
<th>10</th>
<th>16</th>
<th>14</th>
<th>2</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>output</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
First pass

For each node, get the sum of all values in its range; propagate sum up from leaves

Will work like parallel sum, but recording intermediate information

```
input
6  4  16  10  16  14  2  8
output

fromleft
range 0,8
sum  76
fromleft
```
The algorithm, part 2

2. Propagate ‘fromleft’ down:
   - Root given a fromLeft of 0
   - Node takes its fromLeft value and
     • Passes its left child the same fromLeft
     • Passes its right child its fromLeft plus its left child’s sum (as stored in part 1)
   - At the leaf for array position i,
     \[ \text{output}[i] = \text{fromLeft} + \text{input}[i] \]

This is an easy fork-join computation: traverse the tree built in step 1 and produce no result (the leaves assign to output)

- Invariant: fromLeft is sum of elements left of the node’s range

Analysis of first step: \( O(n) \) work, \( O(\log n) \) span

Analysis of second step:

Total for algorithm:
The algorithm, part 2

2. Propagate ‘fromleft’ down:
   - Root given a fromLeft of 0
   - Node takes its fromLeft value and
     • Passes its left child the same fromLeft
     • Passes its right child its fromLeft plus its left child’s sum (as stored in part 1)
   - At the leaf for array position i,
     \[ \text{output}[i] = \text{fromLeft} + \text{input}[i] \]

This is an easy fork-join computation: traverse the tree built in step 1 and produce no result (the leaves assign to output)
   - Invariant: fromLeft is sum of elements left of the node’s range

Analysis of first step: \( O(n) \) work, \( O(\log n) \) span
Analysis of second step: \( O(n) \) work, \( O(\log n) \) span
Total for algorithm: \( O(n) \) work, \( O(\log n) \) span
Second pass

Using ‘sum’, get the sum of everything to the left of this range (call it ‘fromleft’); propagate down from root.
Sequential cut-off

Adding a sequential cut-off isn’t too bad:

- **Step One**: Propagating Up the **sums**:
  - Have a leaf node just hold the sum of a range of values instead of just one array value (Sequentially compute sum for that range)
  - The tree itself will be shallower

- **Step Two**: Propagating Down the **fromLefts**:
  - Have leaf compute prefix sum sequentially over its [lo,hi):
    
    ```
    output[lo] = fromLeft + input[lo];
    for (i = lo + 1; i < hi; i++)
        output[i] = output[i - 1] + input[i]
    ```
Parallel prefix, generalized

Just as sum-array was the simplest example of a common pattern, prefix-sum illustrates a pattern that arises in many, many problems

- Minimum, maximum of all elements to the left of \( i \)
- Is there an element to the left of \( i \) satisfying some property?
- Count of elements to the left of \( i \) satisfying some property
  - This last one is perfect for an efficient parallel pack…
  - Perfect for building on top of the “parallel prefix trick”
Pack (think “Filter”)

[Non-standard terminology]

Given an array input, produce an array output containing only elements such that \( f(\text{element}) \) is true.

Example: input \([17, 4, 6, 8, 11, 5, 13, 19, 0, 24]\)

\( f: \) “is element > 10”

output \([17, 11, 13, 19, 24]\)

Parallelizable?

- Determining whether an element belongs in the output is easy.
- But determining where an element belongs in the output is hard; seems to depend on previous results…. 
Parallel Pack =
parallel map + parallel prefix + parallel map

1. Parallel map to compute a bit-vector for true elements:

   input  [17, 4, 6, 8, 11, 5, 13, 19, 0, 24]
   bits   [1, 0, 0, 0, 1, 0, 1, 1, 0, 1]

2. Parallel-prefix sum on the bit-vector:

   bitsum  [1, 1, 1, 1, 2, 2, 3, 4, 4, 5]

3. Parallel map to produce the output:

   output  [17, 11, 13, 19, 24]

   output = new array of size bitsum[n-1]
   FORALL (i=0; i < input.length; i++){
     if(bits[i]==1)
       output[bitsum[i]-1] = input[i];
   }

In this example, Filter =
element > 10
Pack comments

• First two steps can be combined into one pass
  – Just using a different base case for the prefix sum
  – No effect on asymptotic complexity

• Can also combine third step into the down pass of the prefix sum
  – Again no effect on asymptotic complexity

• Analysis: $O(n)$ work, $O(\log n)$ span
  – 2 or 3 passes, but 3 is a constant 😊

• Parallelized packs will help us parallelize quicksort…
**Sequential Quicksort review**

Recall quicksort was sequential, in-place, expected time $O(n \log n)$

1. Pick a pivot element \( O(1) \)
2. Partition all the data into:
   A. The elements less than the pivot \( O(n) \)
   B. The pivot
   C. The elements greater than the pivot
3. Recursively sort A and C \( 2T(n/2) \)

Recurrence (assuming a good pivot):
\[
T(0)=T(1)=1 \\
T(n)=n + 2T(n/2) = O(n \log n)
\]

Run-time: \( O(n \log n) \)

How should we parallelize this?
Review: Really common recurrences

Should know how to solve recurrences but also recognize some really common ones:

\[
T(n) = O(1) + T(n-1) \quad \text{linear}
\]
\[
T(n) = O(1) + 2 T(n/2) \quad \text{linear}
\]
\[
T(n) = O(1) + T(n/2) \quad \text{logarithmic}
\]
\[
T(n) = O(1) + 2 T(n-1) \quad \text{exponential}
\]
\[
T(n) = O(n) + T(n-1) \quad \text{quadratic}
\]
\[
T(n) = O(n) + T(n/2) \quad \text{linear}
\]
\[
T(n) = O(n) + 2 T(n/2) \quad O(n \log n)
\]

Note big-Oh can also use more than one variable
• Example: can sum all elements of an \( n \)-by-\( m \) matrix in \( O(nm) \)
Parallel Quicksort (version 1)

1. Pick a pivot element
2. Partition all the data into:
   A. The elements less than the pivot
   B. The pivot
   C. The elements greater than the pivot
3. Recursively sort A and C

First: Do the two recursive calls in parallel
- **Work**: unchanged of course, $O(n \log n)$
- **Span**: now recurrence takes the form:
  $$ T(n) = O(n) + 1T(n/2) = O(n) $$
  **Span**: $O(n)$
- So parallelism (i.e., work/span) is $O(\log n)$

Best / expected case work

<table>
<thead>
<tr>
<th></th>
<th>O(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$O(n)$</td>
<td>$O(n)$</td>
</tr>
</tbody>
</table>

2T(n/2)
Doing better

- $O(\log n)$ speed-up with an infinite number of processors is okay, but a bit underwhelming
  - Sort $10^9$ elements 30 times faster

- Google searches strongly suggest quicksort cannot do better because the partition cannot be parallelized
  - The Internet has been known to be wrong 😊
  - But we need auxiliary storage (no longer in place)
  - In practice, constant factors may make it not worth it, but remember Amdahl’s Law…(exposing parallelism is important!)

- Already have everything we need to parallelize the partition…
Parallel partition (not in place)

Partition all the data into:
A. The elements less than the pivot
B. The pivot
C. The elements greater than the pivot

- This is just two packs!
  - We know a pack is $O(n)$ work, $O(\log n)$ span
  - Pack elements less than pivot into left side of aux array
  - Pack elements greater than pivot into right size of aux array
  - Put pivot between them and recursively sort
  - With a little more cleverness, can do both packs at once but no effect on asymptotic complexity

- With $O(\log n)$ span for partition, the total span for quicksort is
  $$T(n) = O(\log n) + 1T(n/2) = O(\log^2 n)$$
Parallel Quicksort Example (version 2)

• Step 1: pick pivot as median of three

![Array](8 1 4 9 0 3 5 2 7 6)

• Steps 2a and 2c (combinable): pack less than, then pack greater than into a second array
  – Fancy parallel prefix to pull this off (not shown)

![Arrays](1 4 0 3 5 2 1 4 0 3 5 2 6 8 9 7)

• Step 3: Two recursive sorts in parallel
  – Can sort back into original array (like in mergesort)

11/15/2013
Parallelize Mergesort?

Recall mergesort: sequential, not-in-place, worst-case $O(n \log n)$

1. Sort left half and right half \[ 2T(n/2) \]
2. Merge results \[ O(n) \]

Just like quicksort, doing the two recursive sorts in parallel changes the recurrence for the Span to $T(n) = O(n) + 1T(n/2) = O(n)$

- Again, Work is $O(n\log n)$, and
- parallelism is $\text{work/span} = O(\log n)$
- To do better, need to parallelize the merge
  - The trick won’t use parallel prefix this time...
Parallelizing the merge

Need to merge two sorted subarrays (may not have the same size)

| 0 1 4 8 9 | 2 3 5 6 7 |

Idea: Suppose the larger subarray has $m$ elements. In parallel:
- Merge the first $m/2$ elements of the larger half with the “appropriate” elements of the smaller half
- Merge the second $m/2$ elements of the larger half with the rest of the smaller half
Parallelizing the merge (in more detail)

Need to merge two *sorted* subarrays (may not have the same size)

**Idea**: Recursively divide subarrays in half, merge halves in parallel

\[
\begin{array}{cccccc}
0 & 4 & 6 & 8 & 9 & 1 & 2 & 3 & 5 & 7 \\
\end{array}
\]

Suppose the larger subarray has *m* elements. In parallel:

- Pick the *median* element of the larger array (here 6) in constant time
- In the other array, use binary search to find the first element greater than or equal to that median (here 7)

Then, in parallel:

- Merge half the larger array (from the median onward) with the upper part of the shorter array
- Merge the lower part of the larger array with the lower part of the shorter array
Example: Parallelizing the Merge

| 0 4 6 8 9 | 1 2 3 5 7 |
Example: Parallelizing the Merge

1. Get median of bigger half: $O(1)$ to compute middle index
Example: Parallelizing the Merge

1. Get median of bigger half: $O(1)$ to compute middle index
2. Find how to split the smaller half at the same value: $O(\log n)$ to do binary search on the sorted small half
Example: Parallelizing the Merge

1. Get median of bigger half: $O(1)$ to compute middle index
2. Find how to split the smaller half at the same value: $O(\log n)$ to do binary search on the sorted small half
3. Size of two sub-merges conceptually splits output array: $O(1)$
Example: Parallelizing the Merge

1. Get median of bigger half: $O(1)$ to compute middle index
2. Find how to split the smaller half at the same value: $O(\log n)$ to do binary search on the sorted small half
3. Two sub-merges conceptually splits output array: $O(1)$
4. Do two submerges in parallel
Example: Parallelizing the Merge

```
0 4 6 8 9
1 2 3 5 7
```

```
merge
0 4 1 2 3 5
```

```
merge
0 4 1 2 3 5
```

```
merge
0 1 2
```

```
merge
4 3 5
```

```
merge
6 8 7
```

```
merge
6 8 7 9
```

```
merge
0 1 2
```

```
merge
4 3 5
```

```
merge
6 8 7 9
```

```
merge
0 1 2 3 4 5 6 7 8 9
```

11/15/2013
Example: Parallelizing the Merge

When we do each merge in parallel:
- we split the bigger array in half
- use binary search to split the smaller array
- And in base case we do the copy
Parallel Merge Pseudocode

Merge(arr[], left₁, left₂, right₁, right₂, out[], out₁, out₂)

    int leftSize = left₂ - left₁
    int rightSize = right₂ - right₁
    // Assert: out₂ - out₁ = leftSize + rightSize
    // We will assume leftSize > rightSize without loss of generality

    if (leftSize + rightSize < CUTOFF)
        sequential merge and copy into out[out₁..out₂]

    int mid = (left₂ - left₁)/2
    binarySearch arr[right1..right2] to find j such that
    arr[j] ≤ arr[mid] ≤ arr[j+1]

    Merge(arr[], left₁, mid, right₁, j, out[], out₁, out₁+mid+j)
    Merge(arr[], mid+1, left₂, j+1, right₂, out[], out₁+mid+j+1, out₂)
Analysis

- **Sequential** mergesort:
  \[ T(n) = 2T(n/2) + O(n) \]  which is \( O(n \log n) \)

- Doing the *two recursive calls in parallel* but a **sequential merge**:
  
  - **Work**: same as sequential
  
  - **Span**: \( T(n) = T(n/2) + O(n) \)  which is \( O(n) \)

- **Parallel merge** makes **work** and **span** harder to compute…
  
  - Each merge step does an extra \( O(\log n) \) binary search to find how to split the smaller subarray
  
  - To merge \( n \) elements total, do two smaller merges of possibly different sizes
  
  - But worst-case split is \( (3/4)n \) and \( (1/4)n \)
    
    - Happens when the two subarrays are of the same size \( (n/2) \) and the “smaller” subarray splits into two pieces of the most uneven sizes possible: one of size \( n/2 \), one of size 0

```
0  4  6  8
```

```
1  2  3  5
```
Analysis continued

For just a parallel merge of $n$ elements:

- **Work** is $T(n) = T(3n/4) + T(n/4) + O(\log n)$ which is $O(n)$
- **Span** is $T(n) = T(3n/4) + O(\log n)$, which is $O(\log^2 n)$
- (neither bound is immediately obvious, but “trust me”)

So for **mergesort** with *parallel merge* overall:

- **Work** is $T(n) = 2T(n/2) + O(n)$, which is $O(n \log n)$
- **Span** is $T(n) = 1T(n/2) + O(\log^2 n)$, which is $O(\log^3 n)$

So parallelism (work / span) is $O(n / \log^2 n)$

- Not quite as good as quicksort’s $O(n / \log n)$
  - But (unlike Quicksort) this is a worst-case guarantee
  - And as always this is just the asymptotic result
