CSE 332: Data Abstractions

Lecture 11:More Hashing

Ruth Anderson
Spring 2014

Today
- Dictionaries
  - Hashing

Hash Tables: Review

- Aim for constant-time (i.e., $O(1)$) **find**, **insert**, and **delete**
  - "On average" under some reasonable assumptions

- A hash table is an array of some fixed size
  - But growable as we'll see

hash table

client | hash table library

E → int → table-index → collision? → collision resolution

0

…

TableSize –1

Hashing Choices

1. Choose a Hash function
2. Choose TableSize
3. Choose a Collision Resolution Strategy from these:
   - Separate Chaining
   - Open Addressing
     - Linear Probing
     - Quadratic Probing
     - Double Hashing

- Other issues to consider:
  - Deletion?
  - What to do when the hash table gets "too full"?

Open Addressing: Linear Probing

- Why not use up the empty space in the table?
- Store directly in the array cell (no linked list)
- How to deal with collisions?
- If `h(key)` is already full,
  - try `(h(key) + 1) % TableSize`. If full,
  - try `(h(key) + 2) % TableSize`. If full,
  - try `(h(key) + 3) % TableSize`. If full…

- Example: insert 38, 19, 8, 109, 10

0	/
1	/
2	/
3	/
4	/
5	/
6	/
7	/
8	38
9	/

Open Addressing: Linear Probing

- Another simple idea: If **h(key)** is already full,
    - try **(h(key) + 1) % TableSize**. If full,
    - try **(h(key) + 2) % TableSize**. If full,
    - try **(h(key) + 3) % TableSize**. If full…

- Example: insert 38, 19, 8, 109, 10

4	/
5	/
6	/
7	/
8	38
9	19

Open addressing

Linear probing is *one example* of open addressing

In general, open addressing means resolving collisions by trying a sequence of other positions in the table.

Trying the *next* spot is called probing
- We just did linear probing:
    - i^{th} probe: `(h(key) + i) % TableSize`
- In general have some probe function `f` and :
    - i^{th} probe: `(h(key) + f(i)) % TableSize`

Open addressing does poorly with high load factor λ
- So want larger tables
- Too many probes means no more *O(1)*

Terminology

We and the book use the terms
- "chaining" or "separate chaining"
- "open addressing"

Very confusingly,
- "open hashing" is a synonym for "chaining"
- "closed hashing" is a synonym for "open addressing"

Open Addressing: Linear Probing

What about **find**? If value is in table? If not there? Worst case?

What about **delete**?

How does open addressing with linear probing compare to separate
chaining?

Open Addressing: Other Operations

insert finds an open table position using a probe function

What about **find**?

- – Must use same probe function to "retrace the trail" for the data
- – Unsuccessful search when reach empty position

What about **delete**?

- – ***Must*** use "lazy" deletion. Why?
 - • Marker indicates "no data here, but don't stop probing"

10	✖	/	23	/	/	16	✖	26

- – Note: **delete** with chaining is plain-old list-remove

Primary Clustering

It turns out linear probing is a *bad idea*, even though the probe function is quick to compute (a good thing)

- Tends to produce *clusters*, which lead to long probe sequences
- Called primary clustering
- Saw the start of a cluster in our linear probing example
[R. Sedgewick]

Analysis of Linear Probing

- **Trivial fact:** For any $\lambda < 1$, linear probing will find an empty slot
  - It is "safe" in this sense: no infinite loop unless table is full

- **Non-trivial facts** we won't prove:
  Average # of probes given λ (in the limit as `TableSize` $\to\infty$)
  - Unsuccessful search:
  $$\frac{1}{2}\left(1 + \frac{1}{(1-\lambda)^2}\right)$$

  - Successful search:
  $$\frac{1}{2}\left(1 + \frac{1}{(1-\lambda)}\right)$$

- This is pretty bad: need to leave sufficient empty space in the table to get decent performance (see chart)

Analysis in chart form

- Linear-probing performance degrades rapidly as table gets full
  - (Formula assumes "large table" but point remains)
- By comparison, separate chaining performance is linear in λ and has no trouble with λ**>1**

Open Addressing: Linear probing

$$(\texttt{h(key)} + \texttt{f(i)})\ \texttt{\% TableSize}$$

- For linear probing:

$$\texttt{f(i) = i}$$

- So probe sequence is:
  - 0th probe: `h(key) % TableSize`
  - 1st probe: `(h(key) + 1) % TableSize`
  - 2nd probe: `(h(key) + 2) % TableSize`
  - 3rd probe: `(h(key) + 3) % TableSize`
  - …
  - ith probe: `(h(key) + i) % TableSize`

Open Addressing: Quadratic probing

- We can avoid primary clustering by changing the probe function…

$$\texttt{(h(key) + f(i)) \% TableSize}$$

 - For quadratic probing:

$$\texttt{f(i) = i}^2$$

 - So probe sequence is:
   - 0th probe: `h(key) % TableSize`
   - 1st probe: `(h(key) + 1) % TableSize`
   - 2nd probe: `(h(key) + 4) % TableSize`
   - 3rd probe: `(h(key) + 9) % TableSize`
   - …
   - i^{th} probe: `(h(key) + i`^{2}`) % TableSize`

- Intuition: Probes quickly "leave the neighborhood"

(47 + 4) % 7 = 2 collision!

(47 + 9) % 7 = 0 collision!

(47 + 16) % 7 = 0 collision!

(47 + 25) % 7 = 2 collision!

Will we ever get a 1 or 4?!?

Another Quadratic Probing Example

insert(47) will always fail here. Why?

0	48
1	
2	5
3	55
4	
5	40
6	76

For all *i*, $(5 + i^2) \% 7$ is 0, 2, 5, or 6

Proof uses induction and

$$(5 + i^2) \% 7 = (5 + (i - 7)^2) \% 7$$

In fact, for all *c* and *k*,

$$(c + i^2) \% k = (c + (i - k)^2) \% k$$

From bad news to good news

Bad News:

- After `TableSize` quadratic probes, we cycle through the same indices

Good News:

- If `TableSize` is *prime* and $\lambda < \frac{1}{2}$, then quadratic probing will find an empty slot in at most `TableSize/2` probes
- So: If you keep $\lambda < \frac{1}{2}$ and `TableSize` is *prime*, no need to detect cycles

- Proof posted in `lecture11.txt` (slightly less detailed proof in textbook)
    - For prime `T` and `0 ≤ i,j ≤ T/2` where `i ≠ j`,

        `(h(key) + i²) % T ≠ (h(key) + j²) % T`

        That is, if T is prime, the first T/2 quadratic probes map to different locations

Quadratic Probing:
Success guarantee for $\lambda < \frac{1}{2}$

- If size is prime and $\lambda < \frac{1}{2}$, then quadratic probing will find an empty slot in size/2 probes or fewer.

  – show for all $0 \leq$ `i,j` $\leq$ `size/2` and `i` $\neq$ `j`

  $$\texttt{(h(x) + i}^2\texttt{) mod size} \neq \texttt{(h(x) + j}^2\texttt{) mod size}$$

  – by contradiction: suppose that for some $i \neq j$:

  $$\texttt{(h(x) + i}^2\texttt{) mod size} = \texttt{(h(x) + j}^2\texttt{) mod size}$$

  $$\Rightarrow \quad \texttt{i}^2 \texttt{ mod size} = \texttt{j}^2 \texttt{ mod size}$$

  $$\Rightarrow \texttt{(i}^2 - \texttt{j}^2\texttt{) mod size} = \texttt{0}$$

  $$\Rightarrow \texttt{[(i + j)(i - j)] mod size} = \texttt{0}$$

  BUT size does not divide `(i-j)` or `(i+j)`

  How can `i+j = 0` or `i+j = size` when:

  $\quad$ `i` $\neq$ `j` $\quad$ and $\quad$ $0 \leq$ `i,j` $\leq$ `size/2`?

  Similarly how can `i-j = 0` or `i-j = size` ?

Clustering reconsidered

- Quadratic probing does not suffer from primary clustering:
No problem if keys initially hash to the same ***neighborhood***

- But it's no help if keys initially hash *to the same **index***
  - Any 2 keys that hash to the same value will have the same series of moves after that
  - Called secondary clustering

- Can avoid secondary clustering with *a probe function that depends on the key*: double hashing…

Open Addressing: Double hashing

Idea: Given two good hash functions *h* and *g*, it is very unlikely that for some *key*, `h(key) == g(key)`

> `(h(key) + f(i)) % TableSize`

- For double hashing:

$$f(i) = i*g(key)$$

- So probe sequence is:
  - 0th probe: `h(key) % TableSize`
  - 1st probe: `(h(key) + g(key)) % TableSize`
  - 2nd probe: `(h(key) + 2*g(key)) % TableSize`
  - 3rd probe: `(h(key) + 3*g(key)) % TableSize`
  - …
  - ith probe: `(h(key) + i*g(key)) % TableSize`

- Detail: Make sure `g(key)` can't be `0`

T = 10 (TableSize)

Hash Functions:

h(key) = key mod T

g(key) = 1 + ((key/T) mod (T-1))

Insert these values into the hash table in this order. Resolve any collisions with double hashing:

13

28

33

147 → **g(147) = 1 + 14 mod 9 = 6**

43 → **g(43) = 1 + 4 mod 9 = 5**

We have a problem:

$3 + 0 = 3$ $3 + \mathbf{5} = \mathbf{8}$ $\mathbf{3 + 10 = 13}$

                         $3 + \mathbf{15} = \mathbf{18}$ $3 + 20 = 23$

Double-hashing analysis

- **Intuition**: Since each probe is "jumping" by `g(key)` each time, we "leave the neighborhood" *and* "go different places from other initial collisions"

But, as in quadratic probing, we could still have a problem where we are not "safe" due to an infinite loop despite room in table

- It is known that this cannot happen in at least one case:

   For primes p and q such that 2 < q < p

   h(key) = key % p

   g(key) = q – (key % q)

More double-hashing facts

- Assume "uniform hashing"
  - Means probability of `g(key1) % p == g(key2) % p` is `1/p`

- Non-trivial facts we won't prove:

  Average # of probes given λ (in the limit as `TableSize` $\rightarrow \infty$)
  - Unsuccessful search (intuitive):
  $$\frac{1}{1-\lambda}$$

  - Successful search (less intuitive):
  $$\frac{1}{\lambda}\log_e\left(\frac{1}{1-\lambda}\right)$$

- Bottom line: unsuccessful bad (but not as bad as linear probing), but successful is not nearly as bad
Charts
Where are we?

- <u>Separate Chaining</u> is easy
  - `find`, `delete` proportional to load factor on average
  - `insert` can be constant if just push on front of list
- <u>Open addressing</u> uses probing, has clustering issues as table fills Why use it:
  - Less memory allocation?
    - Some run-time overhead for allocating linked list (or whatever) nodes; open addressing could be faster
  - Easier data representation?
- Now:
  - Growing the table when it gets too full (aka "rehashing")
  - Relation between hashing/comparing and connection to Java

Rehashing

- As with array-based stacks/queues/lists, if table gets too full, create a bigger table and copy everything over

- With **separate chaining,** we get to decide what "too full" means
  - Keep load factor reasonable (e.g., < 1)?
  - Consider average or max size of non-empty chains?
- For **open addressing**, half-full is a good rule of thumb

- New table size
  - Twice-as-big is a good idea, except, uhm, that won't be prime!
  - So go *about* twice-as-big
  - Can have a list of prime numbers in your code since you probably won't grow more than 20-30 times, and then calculate after that

More on rehashing

- What if we copy all data to the same indices in the new table?
  - Will not work; we calculated the index based on `TableSize`

- Go through table, do standard insert for each into new table
  - Iterate over old table: O(n)
  - n inserts / calls to the hash function: $n \cdot O(1) = O(n)$

- Is there some way to avoid all those hash function calls?
  - Space/time tradeoff: Could store `h(key)` with each data item
  - Growing the table is still *O(n)*; only helps by a constant factor

Hashing and comparing

- Our use of int key can lead to us overlooking a critical detail:
  - We initially *hash* **E** to get a table index
  - While chaining or probing we *compare* to **E**
    - Just need equality testing (i.e., "is it what I want")

- So a hash table needs a hash function and a comparator
  - In Project 2, you will use two function objects
  - The Java library uses a more object-oriented approach: each object has an **equals** method and a **hashCode** method

```java
class Object {
  boolean equals(Object o) {…}
  int hashCode() {…}
  …
}
```

Equal objects must hash the same

- The Java library (and your project hash table) make a very important assumption that clients must satisfy…

- Object-oriented way of saying it:

    If `a.equals(b)`, then we must require
    `a.hashCode()==b.hashCode()`

- Function object way of saying it:

    If `c.compare(a,b) == 0`, then we must require

    `h.hash(a) == h.hash(b)`

- If you ever override equals
    – You need to override hashCode also in a consistent way
    – See CoreJava book, Chapter 5 for other "gotchas" with equals

By the way: comparison has rules too

We have not emphasized important "rules" about comparison for:
- All our dictionaries
- Sorting (next major topic)

Comparison must impose a consistent, total ordering:

For all `a`, `b`, and `c`,
- If `compare(a,b) < 0`, then `compare(b,a) > 0`
- If `compare(a,b) == 0`, then `compare(b,a) == 0`
- If `compare(a,b) < 0` and `compare(b,c) < 0`,
  then `compare(a,c) < 0`

A Generally Good hashCode()

int result = 17; // start at a prime

foreach field f
   int fieldHashcode =
      boolean: (f ? 1: 0)
      byte, char, short, int: (int) f
      long: (int) (f ^ (f >>> 32))
      float: Float.floatToIntBits(f)
      double: Double.doubleToLongBits(f), then above
      Object: object.hashCode( )

      result = 31 * result + fieldHashcode;
 return result;

Final word on hashing

- The hash table is one of the most important data structures
  - Efficient find, insert, and delete
  - Operations based on sorted order are not so efficient
  - Useful in many, many real-world applications
  - Popular topic for job interview questions
- Important to use a good hash function
  - Good distribution, Uses enough of key's values
  - Not overly expensive to calculate (bit shifts good!)
- Important to keep hash table at a good size
  - Prime #
  - Preferable λ depends on type of table
- What we skipped: Perfect hashing, universal hash functions, hopscotch hashing, cuckoo hashing
- Side-comment: hash functions have uses beyond hash tables
  - Examples: Cryptography, check-sums
