CSE 333
Lecture 7 - final C details

Hal Perkins
Department of Computer Science & Engineering
University of Washington
Administrivia

New exercise posted this morning, due before class Wed.

- A little longer and a few more days than usual because...

No class Monday (MLK holiday)

Lecture order rearranged to finish most C topics today before the long weekend (lec 7 before lec 6)

- (Instructor is too lazy to renumber everything.)

HW1 due a week from Tuesday

- Not much discussion board traffic yet. No problems, no confusion, or nobody started?
Agenda

Today’s topics:

- a few final C details
  - header guards and other preprocessor tricks
  - extern, static and visibility of symbols
  - some topics for you to research on your own
an #include problem

What happens when we compile foo.c?

typedef void *LinkedList;
// more definitions below

#include "ll.h"
#include "ht.h"

int main(int argc, char **argv) {
    // ... do stuff here ...
    return 0;
}

foo.c
an #include problem

What happens when we compile foo.c?

bash$ gcc -Wall -g -o foo foo.c

In file included from ht.h:1, 
    from foo.c:2:
ll.h:1: error: redefinition of typedef 'LinkedList'
ll.h:1: note: previous declaration of 'LinkedList' was here

foo.c includes ll.h twice!

- 2nd time is indirectly via ht.h
- so, typedef shows up twice!
- try using cpp to see this
header guards

A commonly used C preprocessor trick to deal with this

- uses macro definition (#define)
- uses conditional compilation (#ifndef and #endif)

```c
#ifndef _LL_H_
#define _LL_H_

typedef void *LinkedList;

// more definitions below

#endif // _LL_H_
```

```c
#ifndef _HT_H_
#define _HT_H_

#include "ll.h"

typedef void *HashTable;

// A hypothetical function
LinkedList HTKeyList(HashTable t);

#endif // _HT_H_
```
Other preprocessor tricks

A way to deal with “magic constants”

```
int globalbuffer[1000];
void circalc(float rad, 
    float *circumf, 
    float *area) {
    *circumf = rad * 2.0 * 3.1415;
    *area = rad * 3.1415 * 3.1415;
}
```

```
#define BUFSIZE 1000
#define PI 3.14159265359
int globalbuffer[BUFSIZE];
void circalc(float rad, 
    float *circumf, 
    float *area) {
    *circumf = rad * 2.0 * PI;
    *area = rad * 3.1415 * PI;
}
```

bad code
(littered with magic constants)

better code
Macros

You can pass arguments to macros

```cpp
#define ODD(x) ((x) % 2 != 0)
void foo(void) {
    if ( ODD(5) )
        printf("5 is odd!\n");
}
```

Be careful of precedence issues; use parenthesis:

```cpp
#define ODD(x) ((x) % 2 != 0)
#define BAD(x) x % 2 != 0
ODD(5 + 1);
BAD(5 + 1);
```
Conditional Compilation

You can change what gets compiled

```c
#define TRACE
#define ENTER(f) printf("Entering %s\n", f);
#define EXIT(f) printf("Exiting %s\n", f);
#else
#define ENTER(f)
#define EXIT(f)
#endif

// print n
void pr(int n) {
    ENTER("pr");
    printf("n = %d\n", n);
    EXIT("pr");
}
```

ifdef.c
Defining Symbols

Besides #defines in the code, preprocessor values can be given on the gcc command

```bash
bash$ gcc -Wall -g -DTRACE -o ifdef ifdef.c
```

assert is controlled the same way - #define NDEBUG and asserts expand to “empty” (it’s a macro - see assert.h)

```bash
bash$ gcc -Wall -g -DNDEBUG -o faster usesassert assert.c
```
Namespace problem

If I define a global variable named “counter” in foo.c, is it visible in bar.c?

- if you use **external linkage**: yes
  - the name “counter” refers to the same variable in both files
  - the variable is defined in one file, declared in the other(s)
  - when the program is linked, the symbol resolves to one location

- if you use **internal linkage**: no
  - the name “counter” refers to different variables in each file
  - the variable must be defined in each file
  - when the program is linked, the symbols resolve to two locations
External linkage

```c
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// It has external linkage by
// default.
int counter = 1;

int main(int argc, char **argv) {
    printf("%d\n", counter);
    bar();
    printf("%d\n", counter);
    return 0;
}
```

foo.c

```c
#include <stdio.h>

// "counter" is defined and
// initialized in foo.c.
// Here, we declare it, and
// specify external linkage
// by using the extern
// specifier.
extern int counter;

void bar(void) {
    counter++;
    printf("(b): counter %d\n",
           counter);
}
```

bar.c

CSE333 lec 7 C.6 // 01-17-14 // Perkins
**Internal linkage**

```c
#include <stdio.h>

// A global variable, defined and initialized here in foo.c.
// We force internal linkage by using the static specifier.
static int counter = 1;

int main(int argc, char **argv) {
    printf("%d\n", counter);
    bar();
    printf("%d\n", counter);
    return 0;
}
```

`foo.c`

```c
#include <stdio.h>

// A global variable, defined and initialized here in bar.c.
// We force internal linkage by using the static specifier.
static int counter = 100;

void bar(void) {
    counter++;
    printf("(b): counter %d\n", counter);
}
```

`bar.c`
Some gotchas

Every global (variables and functions) is extern by default

- unless you specify the static specifier, if some other module uses the same name, you’ll end up with a collision!
  - best case: compiler error
  - worst case: stomp all over each other

- it’s good practice to:
  - use static to defend your globals (hide your private stuff!)
  - place external (i.e., global) declarations in a module’s header file
Extern, static functions

// By using the static specifier, we are indicating
// that foo() should have internal linkage. Other
// .c files cannot see or invoke foo().
static int foo(int x) {
    return x*3 + 1;
}

// Bar is "extern" by default. Thus, other .c files
// could declare our bar() and invoke it.
int bar(int x) {
    return 2*foo(x);
}

#include <stdio.h>

extern int bar(int);

int main(int argc, char **argv) {
    printf("%d\n", bar(5));
    return 0;
}
Somebody should get fired

C has a second, different use for the word “static”

- to declare the extent of a local variable

- if you declare a static local variable, then:
  
  ▷ the storage for that variable is allocated when the program loads, in either the program’s .data or .bss segment

  ▷ the variable retains its value across multiple function invocations

(see static_extent.c for an example)
Additional C topics

Teach yourself

- bit-level manipulation in C (cf CSE 351): \texttt{\textasciitilde | \& << >>}
- string library functions provided by the C standard library
  - #include <string.h>
    - strlen( ), strcpy( ), strdup( ), strcat( ), strcmp( ), strchr( ), strstr( ), ...
    - learn why \texttt{strncat} is safer (in the security sense) than \texttt{strcat}, etc.
  - #include <stdlib.h> or #include <stdio.h>
    - atoi( ), atof( ), sprintf( ), sscanf( )
- \texttt{man} pages are your friend!
Additional C topics

Teach yourself
- the syntax for function pointers, including passing as args
- how to declare, define, and use a function that accepts a variable-lengthed number of arguments (varargs)
- unions and what they are good for
- what argc and argv are for in main

```c
#include <stdio.h>

int main(int argc, char **argv) {
    int i;
    for (i = 0; i < argc, i++) {
        printf("%d: %s\n", i, argv[i]);
    }
    return 0;
}
```

```bash
bash$ gcc -o argv argv.c
bash$ ./argv
0: ./argv
bash$ ./argv foo bar
0: ./argv
1: foo
2: bar
bash$
```
Additional C topics

Teach yourself:

- the difference between pre-increment (++v) and post-increment (v++)

- the meaning of the “register” storage class
  ‣ Might see it in code, but compilers often ignore it these days since they can often do a better job without it

- harder: the meaning of the “volatile” storage class
  ‣ pages 91, 92 of CARM, much more precise in C11
Exercise 1

Write a program that:

- prompts the user to input a string (use fgets( ))
  ‣ assume the string is a sequence of whitespace-separated integers
  ‣ e.g., “5555 1234 4 5543”
- converts the string into an array of integers
- converts an array of integers into an array of strings
  ‣ where each element of the string array is the binary representation
    of the associated integer
- prints out the array of strings
Exercise 2

Modify the linked list code from last lecture / exercise 1

- add static declarations to any internal functions you implemented in linkedlist.h
- add a header guard to the header file
- write a Makefile
  - use Google to figure out how to add rules to the Makefile to produce a library (liblinkedlist.a) that contains the linked list code
See you on Wednesday!
