CSE 333
Lecture 11 - constructor insanity

Hal Perkins
Department of Computer Science & Engineering
University of Washington
Administrivia

HW2 out now, due a week from Tuesday

Midterm the following Friday

- Everything up to C++ basics (e.g., exercises)
- Topic list on web site (will update as needed next week depending on where we get to by then)

New exercise posted today, due Monday before class
Today’s goals

More details on constructors, destructors, operators

Walk through complex_example/

- pretty hairy and complex
- a lesson on why using a subset of C++ is often better

new / delete / delete[]

- str/ example
Constructors

A constructor initializes a newly instantiated object

- a class can have multiple constructors
  ‣ they differ in the arguments that they accept
  ‣ which one is invoked depends on how the object is instantiated

You can write constructors for your object

- but if you don’t write any, C++ might automatically synthesize a default constructor for you
  ‣ the default constructor is one that takes no arguments and that calls default constructors on all non-POD member variables
  ‣ C++ does this iff your class has no const or reference data members, and no other user-defined constructors
Example of synthesis

see SimplePoint.cc, SimplePoint.h
Constructors, continued

You might choose to define multiple constructors:

```cpp
Point::Point() {
    x_ = 0;
    y_ = 0;
}

Point::Point(const int x, const int y) {
    x_ = x;
    y_ = y;
}

void foo() {
    Point x;  // invokes the default (argument-less) constructor
    Point y(1,2);  // invokes the two-int-arguments constructor
}
```
Constructors, continued

You might choose to define only one:

```cpp
Point::Point(const int x, const int y) {
    x_ = x;
    y_ = y;
}

void foo() {
    // Compiler error; if you define any constructors, C++ will
    // not automatically synthesize a default constructor for you.
    Point x;

    // Works.
    Point y(1,2); // invokes the two-int-arguments constructor
}
```
Initialization lists

As shorthand, C++ lets you declare an initialization list as part of your constructor declaration:

- initializes fields according to parameters in the list
- the following two are (nearly) equivalent:

```cpp
Point::Point(const int x, const int y) : x_(x), y_(y) {
    std::cout << "Point constructed: (" << x_ << ",";
    std::cout << y_ << ")" << std::endl;
}

Point::Point(const int x, const int y) {
    x_ = x;
    y_ = y;
    std::cout << "Point constructed: (" << x_ << ",";
    std::cout << y_ << ")" << std::endl;
}
```
Initialization vs. construction

When a new object is created using some constructor:

- first, the initialization list is applied to members
  - in the order that those members appear within the class definition, not the order in the initialization list (!)
- next, the constructor is invoked, and any statements within it that affect members are executed

Prefer initializations to assignment

- Objects are initialized by some constructor before they can be assigned - initializer avoids two separate steps
Initialization vs. construction

```cpp
#ifndef _POINT_H_
#define _POINT_H_

class Point {
 public:
  Point(const int x, const int y, const int z)
      : x_(x), y_(y) {
    z_ = z;
  }
 private:
  int x_, y_, z_;
};  // class Point
#endif  // _POINT_H_
```
Initialization vs. construction

```cpp
#ifndef _POINT_H_
#define _POINT_H_

class Point {
  public:
    Point(const int x, const int y, const int z)
      : x_(x), y_(y) {
      z_ = z;
    }

  private:
    int x_, y_, z_;  
};  // class Point

#endif  // _POINT_H_
```

First, initialization list is applied.
Initialization vs. construction

```cpp
#ifndef _POINT_H_
#define _POINT_H_

class Point {
 public:
  Point(const int x, const int y, const int z)
      : x_(x), y_(y) {
    z_ = z;
  }
 private:
  int x_, y_, z_;  
};  // class Point
#endif  // _POINT_H_
```

next, constructor is executed
Copy constructors

C++ has the notion of a copy constructor
- used to create a new object as a copy of an existing object

Point::Point(const int x, const int y) : x_(x), y_(y) { }
Point::Point(const Point &copyme) {  // copy constructor
    x_ = copyme.x_;  
    y_ = copyme.y_;  
}

void foo() {
    // invokes the two-int-arguments constructor
    Point x(1,2);

    // invokes the copy constructor to construct y as a copy of x
    Point y(x);  // could also write as “Point y = x;”
}
When do copies happen?

The copy constructor is invoked if:

- you pass an object as a parameter to a call-by-value function

```cpp
void foo(Point x) { ... }
Point y; // default cons.
foo(y); // copy cons.
```

- you return an object from a function

```cpp
Point foo() {
    Point y; // default cons.
    return y; // copy cons.
}
```

- you initialize an object from another object of the same type

```cpp
Point x; // default cons.
Point y(x); // copy cons.
Point z = y; // copy cons.
```
But...the compiler is smart...

It sometimes uses a “return by value optimization” to eliminate unnecessary copies

- sometimes you might not see a constructor get invoked when you expect it

```cpp
Point foo() {
    Point y; // default constructor.
    return y; // copy constructor? optimized?
}
Point x(1,2); // two-ints-argument constructor.
Point y = x; // copy constructor.
Point z = foo(); // copy constructor? optimized?
```
Synthesized copy constructor

If you don’t define your own copy constructor, C++ will synthesize one for you

- it will do a shallow copy of all of the fields (i.e., member variables) of your class
- sometimes the right thing, sometimes the wrong thing

see SimplePoint.cc, SimplePoint.h
The “=” operator is the assignment operator

- assigns values to an existing, already constructed object
- you can overload the “=” operator

```cpp
Point w;            // default constructor.
Point x(1, 2);     // two- ints- argument constructor.
Point y = w;       // copy constructor.
y = x;             // assignment operator.
```
Overloading the “=” operator

You can choose to overload the “=” operator

- but there are some rules you should follow

```cpp
Point &Point::operator=(const Point& rhs) {
    if (this != &rhs) { // always check against this
        x_ = rhs.x_;  
        y_ = rhs.y_;  
    }
    return *this;  // always return *this from =
}

Point a; // default constructor
a = b = c; // works because “=” returns *this
a = (b = c); // equiv to above, as “=” is right-associative
(a = b) = c; // works because “=” returns a non-const
```
Synthesized assignment oper.

If you don’t overload the assignment operator, C++ will synthesize one for you

- it will do a shallow copy of all of the fields (i.e., member variables) of your class

- sometimes the right thing, sometimes the wrong thing

see SimplePoint.cc, SimplePoint.h
Destructors

C++ has the notion of a destructor

- invoked automatically when a class instance is deleted / goes out of scope, etc., even via exceptions or other causes

- place to put cleanup code - free any dynamic storage or other resources owned by the object

- standard C++ idiom for managing dynamic resources

  ‣ Slogan: “Resource Acquisition Is Initialization” (RAII)

```cpp
Point::~Point() {  // destructor
    // do any cleanup needed when a Point object goes away
    // (nothing to do here since we have no dynamic resources)
}
```
see complex_example/*
Dealing with the insanity

C++ style guide tip

- if possible, disable the copy const. and assignment operator
  
  ‣ *not possible if you want to store objects of your class in an STL container, unfortunately*

```cpp
class Point {
public:
    Point(int x, int y) : x_(x), y_(y) { }

private:
    // disable copy cons. and "=" by declaring but not defining
    Point(Point &copyme);
    Point &operator=(Point &rhs);
};

Point w;       // compiler error
Point x(1,2);   // OK
Point y = x;    // compiler error
x = w;         // compiler error
```
Dealing with the insanity

C++ style guide tip

- if you disable them, then you should instead have an explicit “CopyFrom” function

```cpp
class Point {
public:
    Point::Point(int x, int y) : x_(x), y_(y) { }
    void CopyFrom(const Point &copy_from_me);

private:
    // disable copy cons. and "=" by declaring but not defining
    Point(const Point &copyme);
    Point &operator=(const Point &rhs);
};
```

```cpp
Point x(1,2); // OK
Point y(3,4); // OK
x.CopyFrom(y); // OK
```

sanepoint.cc
new

To allocate on the heap using C++, you use the “new” keyword instead of the “malloc( )” stdlib.h function

- you can use new to allocate an object
- you can use new to allocate a primitive type

To deallocate a heap-allocated object or primitive, use the “delete” keyword instead of the “free( )” stdlib.h function

- if you’re using a legacy C code library or module in C++
  ▸ if C code returns you a malloc( )’d pointer, use free( ) to deallocate it
  ▸ **never** free( ) something allocated with new
  ▸ **never** delete something allocated with malloc( )
new / delete

see heapoint.cc
C++11 nullptr

C and C++ have long used NULL as a pointer value that references nothing

C++11 introduces a new literal for this: nullptr

- New reserved word
- Interchangeable with NULL for all practical purposes
  - But it has type T* for any/every T, and is not an integer value
    - Avoids funny edge cases (see C++ references for details)
    - Still can convert to/from integer 0 for tests, assignment, etc.
- Use nullptr in new C++11 code, but NULL will also be around for a long, long time.
Dynamically allocated arrays

To dynamically allocate an array

- use "type *name = new type[size];"

To dynamically deallocate an array

- use "delete[] name;"

- it is an error to use "delete name;" on an array
  ‣ the compiler probably won’t catch this, though!!!
  ‣ it can’t tell if it was allocated with "new type[size];" or "new type;"

see arrays.cc
### malloc vs. new

<table>
<thead>
<tr>
<th></th>
<th>malloc( )</th>
<th>new</th>
</tr>

<tbody>
<tr>
<td><strong>what is it</strong></td>
<td>a function</td>
<td>an operator and keyword</td>
</tr>
<tr>
<td><strong>how often used in C</strong></td>
<td>often</td>
<td>never</td>
</tr>
<tr>
<td><strong>how often used in C++</strong></td>
<td>rarely</td>
<td>often</td>
</tr>
<tr>
<td><strong>allocates memory for</strong></td>
<td>anything</td>
<td>arrays, structs, objects, primitives</td>
</tr>
<tr>
<td><strong>returns</strong></td>
<td>a (void *) <em>(needs a cast)</em></td>
<td>appropriate pointer type <em>(doesn’t need a cast)</em></td>
</tr>
<tr>
<td><strong>when out of memory</strong></td>
<td>returns NULL</td>
<td>throws an exception</td>
</tr>
<tr>
<td><strong>deallocating</strong></td>
<td>free</td>
<td>delete or delete[]</td>
</tr>
</tbody>
</table>
Overloading the "=" operator

Remember the rules we should follow?

- here's why; hugely subtle bug

```cpp
Foo::Foo(int val) { Init(val); }
Foo::~Foo() { delete my_ptr_; }

void Foo::Init(int val) { my_ptr_ = new int; *my_ptr_ = val; }

Foo &Foo::operator=(const Foo& rhs) {
    // bug...we forgot our "if (self == &rhs) { ... }" guard
    delete my_ptr_;  
    Init(* (rhs.my_ptr_));  // might crash here (see below)
    return *this; // always return *this from =
}

void bar() {
    Foo a(10);  // default constructor
    Foo b(20);  // default constructor
    a = a;     // crash above; dereference delete'd pointer!!
}
```
Overloading the “=” operator

Remember the rules we should follow?

This is yet another reason for disabling the assignment operator, when possible
see str/*
Exercise 1

Modify your 3D Point class from lec10 exercise 1

- disable the copy constructor and assignment operator
- attempt to use copy & assign in code, and see what error the compiler generates
- write a CopyFrom() member function, and try using it instead
Exercise 2

Write a C++ class that:

- is given the name of a file as a constructor argument
- has a “GetNextWord( )” method that returns the next whitespace or newline-separate word from the file as a copy of a “string” object, or an empty string once you hit EOF.
- has a destructor that cleans up anything that needs cleaning up
Exercise 3

Write a C++ function that:

- uses new to dynamically allocate an array of strings
  - and uses delete[ ] to free it

- uses new to dynamically allocate an array of pointers to strings
  - and then iterates through the array to use new to allocate a string for each array entry and to assign to each array element a pointer to the associated allocated string
  - and then uses delete to delete each allocated string
  - and then uses delete[ ] to delete the string pointer array
  - (whew!)
See you on Monday!
