CSE 333
Lecture 9 - intro to C++

Hal Perkins
Department of Computer Science & Engineering
University of Washington
Administrivia

New exercise posted after sections tomorrow, due Monday morning

- Read a directory and open/copy text files found there
- Good warmup for …

HW2

- Writeup posted tomorrow, starter files pushed Friday
- Short demo in class Friday
Today’s goals

An introduction to C++
- some shortcomings of C that C++ addresses
- give you a perspective on how to learn C++
- kick the tires and write some code

Advice: read related sections in the C++ *Primer*. It’s hard to learn the “why it is done like this” from reference docs
- Lectures and examples introduce main ideas, but aren’t everything you’ll want need to understand
We had to work hard to mimic encapsulation, abstraction

- **encapsulation**: hiding implementation details
  - used header file conventions and the “static” specifier to separate private functions from public functions
  - cast structures to (void *) to hide implementation-specific details

- **abstraction**: associating behavior with encapsulated state
  - the functions that operate on a LinkedList were not really tied to the linked list structure
  - we passed a linked list to a function, rather than invoking a method on a linked list instance
C++

A major addition is its support for classes & objects!

- classes
  - public, private, and protected **methods** and **instance variables**
  - (multiple!) inheritance

- polymorphism
  - **static polymorphism**: multiple functions or methods with the same name, but different argument types (overloading)
    - Works for all functions, not just class members
  - **dynamic (subtype) polymorphism**: derived classes can override methods of parents, and methods will be dispatched correctly
We had to emulate generic data structures

- customer passes a (void *) as a payload to a linked list
- customer had to pass in function pointers so that the linked list could operate on payloads correctly
  ▸ comparisons, deallocation, pickling up state, etc.
C++

Supports **templates** to facilitate generic data types!

- Parametric polymorphism - same idea as Java generics, but different in details - particularly implementation

  - to declare that `x` is a vector of ints:
    
    ```
    vector<int> x;
    ```

  - to declare that `x` is a vector of floats:
    
    ```
    vector<float> x;
    ```

  - to declare that `x` is a vector of (vectors of floats):
    
    ```
    vector<vector<float>> x;
    ```
We had to be careful about namespace collisions

- C distinguishes between external and internal linkage
  ‣ use “static” to prevent a name from being visible outside a source file (as close as C gets to “private”)
  ‣ otherwise, a name is global -- visible everywhere

- we used naming conventions to help avoid collisions in the global namespace
  ‣ LLIteratorNext, HTIteratorNext, etc.
C++

Permits a module to define its own namespace!
- the linked list module could define an “LL” namespace
- the hashtable module could define an “HT” namespace
- both modules could define an Iterator class
  ‣ one would be globally named LL::Iterator
  ‣ the other would be globally named HT::Iterator

Classes also allow duplicate names without collisions
- Namespaces group & isolate names in collections of classes and other “global” things (somewhat like Java packages)
C does not provide any standard data structures

- we had to implement our own linked list and hash table
- as a C programmer, you often re-invent the wheel badly
  - maybe if you’re clever you’ll use somebody else’s libraries
  - but, C’s lack of abstraction, encapsulation, and generics means you’ll probably have to tweak them, or tweak your code to use them
The C++ standard library is huge!

- **generic containers**: bitset, queue, list, associative array (including hash table), deque, set, stack, and vector
  
  ‣ and iterators for most of these

- **a string class**: hides the implementation of strings

- **streams**: allows you to stream data to and from objects, consoles, files, strings, and so on

- and more...
Error handling is a pain

- have to define error codes and return them
- customers have to understand error code conventions, and need to constantly test return values
- if a() calls b() calls c()
  ‣ a depends on b to propagate an error in c back to it
C++

Supports exceptions!
- try / throw / catch

if used with discipline, can simplify error processing
- but, if used carelessly, can complicate memory management
- consider: a() calls b() calls c()
  - if c() throws an exception that b() doesn’t catch, you might not get a chance to clean up resources allocated inside b()

But much C++ code still needs to work with C & old C++ libraries, so still uses return codes, exit(), etc.
Some tasks still hurt in C++

Memory management

- C++ has no garbage collector
  
  ‣ you have to manage memory allocation and deallocation, and track ownership of memory
  
  ‣ it’s still possible to have leaks, double frees, and so on

- but, there are some things that help
  
  ‣ “smart pointers”
    
    • classes that encapsulate pointers and track reference counts
    
    • deallocate memory when the reference count goes to zero
Some tasks still hurt in C++

C++ doesn’t guarantee type or memory safety

- You can still...
  - forcibly cast pointers between incompatible types
  - walk off the end of an array and smash the stack (or heap)
  - have dangling pointers
  - conjure up a pointer to an address of your choosing
C++ has many, many features.

**Operator overloading**
- your class can define methods for handling “+”, “->”, etc!

**Object constructors, destructors**
- particularly handy for stack-allocated objects

**Reference types**
- truly pass-by-reference instead of pass-by-value

**Advanced OO**
- multiple inheritance, virtual base classes, dynamic dispatch
How to think about C++

set of styles and ways to use C++

style guides

good styles and robust engineering practices

set of styles and ways to use C
Or...

in the hands of a
disciplined programmer,
C++ is a powerful weapon

but, if you’re not so
disciplined about how
you use C++...
Hello, world!

```
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

Looks simple enough...

- compile with g++ instead of gcc:
  
  - g++ -Wall -g -std=c++11 -o helloworld helloworld.cc

- let’s walk through the program step by step
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

iostream is part of the C++ standard library

- note you don’t include a “.h” when you include C++ standard library headers
  - but you do for local headers (e.g., #include “ll.h”)

- iostream declares stream object instances, including std::cin, std::cout, std::cerr, in the “std” namespace
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

`std::cout` is the “cout” object instance declared by iostream, living within the “std” namespace (C++’s name for stdout)

- `std::cout` is an object of class `ostream`
- used to format and write output to the console
- the entire standard library is in namespace `std`
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

C++ distinguishes between objects and primitive types

- primitive types include all the familiar ones from C
  - char, short, int, unsigned long, float, double, long double, etc.
  - and, C++ defines “bool” as a primitive type (woohoo!)
Hello, world!

“<<” is an operator defined by the C++ language
- it’s defined by C as well; in C/C++, it bitshifts integers
- but, C++ allows classes to overload operators
  ‣ the ostream class overloads “<<”
  ‣ i.e., it defines member functions (methods) that are invoked when an ostream is the LHS of the << operator
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

`<ostream>` has many different functions to handle `<<`
- the functions differ in the type of the RHS of `<<`
- if you do `std::cout << "foo";`
  - C++ invokes cout’s function to handle `"<<"` with RHS “char *”
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

the ostream class’s member functions that handle “<<” return (a reference to) themselves

- so, when (std::cout << “Hello, World!”) is evaluated:
  - a member function of the std::cout object is invoked
  - it buffers the string “Hello, World!” for the console
  - and, it returns (a reference to) std::cout
Hello, world!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```

next, a member function on std::cout to handle "<<" is invoked
- this time, the RHS is std::endl
- turns out this is a pointer to a “manipulator” function
  - this manipulator function writes newline to the ostream it is invoked on, and then flushes the ostream’s buffer
  - so, something is printed on the console at this point
Wow...

You should be surprised and scared at this point

- C++ makes it easy to hide a significant amount of complexity
  - it’s powerful, but really dangerous
  - once you mix together templates, operator overloading, method overloading, generics, and multiple inheritance, it gets really hard to know what’s actually happening!

```cpp
#include <iostream>
#include <cstdlib>

int main(int argc, char **argv) {
    std::cout << "Hello, World!" << std::endl;
    return EXIT_SUCCESS;
}
```
Refining it a bit...

C++’s standard library has a `std::string` class!

- include the `<string>` header to use it

```cpp
#include <iostream>
#include <cstdlib>
#include <string>
using namespace std;

int main(int argc, char **argv) {
    string hello("Hello, World!");
    cout << hello << endl;
    return EXIT_SUCCESS;
}
```
Refining it a bit...

The “using” keyword introduces part of a namespace, or an entire namespace, into the current region

- using namespace std;   -- imports all names from std::
- using std::cout;   -- imports only std::cout
Refining it a bit...

We’re instantiating a `std::string` object on the stack

- passing the C string “Hello, World!” to its constructor method
  - `hello` is deallocated (and its destructor invoked) when main returns
Refining it a bit...

The C++ string library overloads the `<<` operator as well:

- defines a function (not an object method) that is invoked when the LHS is an ostream and the RHS is a `std::string`

Refining it a bit...

Note the side-effect of `using namespace std;`

- can now refer to `std::string` by `string`, `std::cout` by `cout`, and `std::endl` by `endl`
The string class overloads the "+" operator

- creates and returns a new string that is the concatenation of LHS and RHS
The string class overloads the "=" operator
- copies the RHS and replaces the string's contents with it

  ‣ so, the full statement (i) "+" creates a string that is the concatenation of hello's current contents and " there", and (ii) "=" creates a copy of the concatenation to store in hello. Without the syntactic sugar it is: hello.operator=(hello.operator+(" there"));
stream manipulators

```cpp
#include <iostream>
#include <cstdlib>
#include <iomanip>
using namespace std;

int main(int argc, char **argv) {
    cout << "Hi! " << setw(4) << 5 << " " << 5 << endl;
    cout << hex << 16 << " " << 13 << endl;
    cout << dec << 16 << " " << 13 << endl;
    return EXIT_SUCCESS;
}
```

iomanip defines a set of stream manipulator functions
- pass them to a stream to affect formatting
stream manipulators

```cpp
#include <iostream>
#include <cstdlib>
#include <iomanip>
using namespace std;

int main(int argc, char **argv) {
    cout << "Hi! " << setw(4) << 5 << " " << 5 << endl;
    cout << hex << 16 << 13 << endl;
    cout << dec << 16 << " " << 13 << endl;
    return EXIT_SUCCESS;
}
```

setw(x) sets the width of the next field to x
- only affects the next thing sent to the output stream
stream manipulators

#include <iostream>
#include <cstdlib>
#include <iomanip>
using namespace std;

int main(int argc, char **argv) {
    cout << "Hi! " << setw(4) << 5 << " " << 5 << endl;
    cout << hex << 16 << " " << 13 << endl;
    cout << dec << 16 << " " << 13 << endl;
    return EXIT_SUCCESS;
}

**hex** sets the stream to output integers in hexadecimal
- stays in effect until you set the stream to some other base
- **hex**, **dec**, **oct** are your choices
You can still use printf, though

C is (roughly) a subset of C++

- Can mix C and C++ idioms if needed to work with existing code, but avoid mixing if you can - use C++(11)
std::cin is an object instance of class istream

- supports the >> operator for “extraction”
- cin also has a getline() method
Exercise 1

Write a C++ program that:

- uses streams to:
  - prompts the user to type in 5 floats
  - prints them out in opposite order
  - with 4 digits of precision
See you on Monday!
