CSE 333
Lecture 12 - templates, STL

Hal Perkins
Department of Computer Science & Engineering
University of Washington
Administrivia

New exercise out today, due Wednesday morning
HW2 due Thursday night, 11 pm.

<panic>if not started yet</panic>
<celebrate>if done</celebrate>

BE SURE TO CHECK YOUR WORK (git clone/checkout, make, tests, …)

No new exercise for Friday
Midterm next Monday, then new exercise, HW3 right after
Today’s goals

Templates and type-independent code

C++’s standard library

STL containers, iterators, algorithms

A few core ones only - see docs & Primer for others
Suppose that...

You want to write a function to compare two ints:

```cpp
// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
int compare(const int &value1, const int &value2) {
    if (v1 < v2) return -1;
    if (v2 < v1) return 1;
    return 0;
}
```
Suppose that...

You want to write a function to compare two ints, and you also want to write a function to compare two strings:

```cpp
// note the cool use of function overloading!

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
int compare(const int &value1, const int &value2) {
    if (value1 < value2) return -1;
    if (value2 < value1) return 1;
    return 0;
}

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
int compare(const string &value1, const string &value2) {
    if (value1 < value2) return -1;
    if (value2 < value1) return 1;
    return 0;
}
```
Hmm....

The two implementations of compare are nearly identical.

we could write a compare for every comparable type

but, that’s obviously a waste; lots of redundant code!

Instead, we’d like to write “generic code”

code that is type-independent

code that is compile-time polymorphic across types
C++: parametric polymorphism

C++ has the notion of templates

- a function or class that accepts a type as a parameter

  - you implement the function or class once, in a type-agnostic way

  - when you invoke the function or instantiate the class, you specify (one or more) types, or values, as arguments to it

- at compile-time, when C++ notices you using a template...

  - the compiler generates specialized code using the types you provided as parameters to the template
Function template

You want to write a function to compare two things:

```cpp
#include <iostream>
#include <string>

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
template <class T>
t int compare(const T &value1, const T &value2) {
    if (value1 < value2) return -1;
    if (value2 < value1) return 1;
    return 0;
}

int main(int argc, char **argv) {
    std::string h("hello"), w("world");
    std::cout << compare<std::string>(h, w) << std::endl;
    std::cout << compare<int>(10, 20) << std::endl;
    std::cout << compare<double>(50.5, 50.6) << std::endl;
    return 0;
}
```
Function template

Same thing, but letting the compiler infer the types:

```cpp
#include <iostream>
#include <string>

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
template <class T>
int compare(const T &value1, const T &value2) {
    if (value1 < value2) return -1;
    if (value2 < value1) return 1;
    return 0;
}

int main(int argc, char **argv) {
    std::string h("hello"), w("world");
    std::cout << compare(10, 20) << std::endl;
    std::cout << compare("Hello", "World") << std::endl; // hmmm...
    std::cout << compare(h, w) << std::endl; // ok
    return 0;
}
```

Function template

You can use non-types (constant values) in a template:

```cpp
#include <iostream>
#include <string>

template <class T, int N>
void printmultiple(const T &value1) {
    for (int i = 0; i < N; ++i)
        std::cout << value1 << std::endl;
}

int main(int argc, char **argv) {
    std::string h("hello");
    printmultiple<std::string,3>(h);
    printmultiple<const char *,4>("hi");
    printmultiple<int,5>(10);
    return 0;
}
```
What’s going on underneath?

The compiler doesn’t generate any code when it sees the templated function

it doesn’t know what code to generate yet, since it doesn’t know what types are involved

When the compiler sees the function being used, then it understands what types are involved

it generates the instantiation of the template and compiles it

the compiler generates template instantiations for each type used as a template parameter

kind of like macro expansion
This creates a problem...

```cpp
#include "compare.h"

using namespace std;

int main(int argc, char **argv) {
    cout << comp<int>(10, 20);  
    cout << endl;
    return 0;
}
```

```cpp
#include <iostream>
#include "compare.h"

int comp(const T& a, const T& b) {
    if (a < b) return -1;
    if (b < a) return 1;
    return 0;
}
```
One solution

```cpp
#ifndef _COMPARE_H_
#define _COMPARE_H_

template <class T>
int comp(const T& a, const T& b) {
    if (a < b) return -1;
    if (b < a) return 1;
    return 0;
}
#endif // COMPARE_H_  compare.h
```

```cpp
#include <iostream>
#include "compare.h"

using namespace std;

int main(int argc, char **argv) {
    cout << comp<int>(10, 20);  
    cout << endl;
    return 0;
}
```
Another solution

```cpp
#include <iostream>
#include "compare.h"
using namespace std;

int main(int argc, char **argv) {
    cout << comp<int>(10, 20);  
    cout << endl;
    return 0;
}
```

```cpp
#ifndef _COMPARE_H_
#define _COMPARE_H_

template <class T>
int comp(const T& a, const T& b);

#include "compare.cc"

#endif // COMPARE_H_
```
Class templates

Templating is useful for classes as well! Imagine we want a class that holds a pair of things

we want to be able to:

- set the value of the first thing, second thing
- get the value of the first thing, second thing
- reverse the order of the things
- print the pair of things
Pair class

```cpp
#include <iostream>
#include <string>

template <class Thing> class Pair {
    public:
        Pair() { }

        Thing &get_first() { return first_; }
        Thing &get_second();
        void set_first(Thing &copyme);
        void set_second(Thing &copyme);
        void Reverse();

    private:
        Thing first_, second_; 
    }
};

#include "Pair.cc"
```
Pair class

template <class Thing> Thing &Pair<Thing>::get_second() {
    return second_
}

template <class Thing> void Pair<Thing>::set_first(Thing &copyme) {
    first_ = copyme;
}

template <class Thing> void Pair<Thing>::set_second(Thing &copyme) {
    second_ = copyme;
}

template <class Thing> void Pair<Thing>::Reverse() {
    // makes *3* copies
    Thing tmp = first_
    first_ = second_
    second_ = tmp;
}
# Pair class

```cpp
#include <iostream>
#include <string>
#include "Pair.h"

int main(int argc, char **argv) {
    Pair<std::string> ps;
    std::string x("foo"), y("bar");

    ps.set_first(x);
    ps.set_second(y);
    ps.Reverse();
    std::cout << ps.get_first() << std::endl;

    return 0;
}
```

C++’s standard library

Consists of four major pieces:

1. The entire C standard library
2. C++’s input/output stream library
   - `std::cin`, `std::cout`, stringstreams, fstreams, etc.
3. C++’s standard template library (STL)
   - Containers, iterators, algorithms (sort, find, etc.), numerics
4. C++’s miscellaneous library
   - Strings, exceptions, memory allocation, localization

http://www.cplusplus.com/reference/
Containers!

- a container is an object that stores (in memory) a collection of other objects (elements)
  - implemented as class templates, so hugely flexible
- several different classes of container
  - sequence containers (vector, deque, list)
  - associative containers (set, map, multiset, multimap, bitset)
- differ in algorithmic cost, supported operations
STL :(  

STL containers store by value, not by reference  
when you insert an object, the container makes a copy  
if the container needs to rearrange objects, it makes copies  
e.g., if you sort a vector, it will make many many copies  
e.g., if you insert into a map, that may trigger several copies  
what if you don’t want this (disabled copy ctr, or copy is $$)?  
you can insert a wrapper object with a pointer to the object  
we’ll learn about these “smart pointers” later
STL vector

A generic, dynamically resizable array

- elements are stored in contiguous memory locations
- elements can be accessed using pointer arithmetic if you like
- random access is $O(1)$ time
- adding / removing from the end is cheap (constant time)
- inserting / deleting from middle or start is expensive ($O(n)$)

Example

see Tracer.cc, Tracer.h, vectorfun.cc
STL iterator

Each container class has an associated iterator class used to iterate through elements of the container (duh!)

some container iterators support more operations than others

all can be incremented (++ operator), copied, copy-cons’ed

some can be dereferenced on RHS (e.g., x = *it;)

some can be dereferenced on LHS (e.g., *it = x;)

some can be decremented (-- operator)

some support random access ([ ], +, -, + =, - =, <, > operators)

http://www.cplusplus.com/reference/std/iterator/
Example

see vectoriterator.cc
Type inference [C++11]

the ‘auto’ keyword can be used to infer types

simplifies your life if, for example, functions return complicated types

the expression using auto must contain explicit initialization for it to work

```cpp
// Calculate and return a vector containing all factors of n
std::vector<int> Factors(int n);

void foo(void) {
    // Manually identified type
    std::vector<int> facts1 = Factors(324234);

    // Inferred type
    auto facts2 = Factors(12321);

    // Compiler error here
    auto facts3;
}
```
Type inference [C++11]

Auto and iterators

life becomes much simpler!

```cpp
for (vector<Tracer>::iterator it = vec.begin(); it < vec.end(); it++) {
    cout << *it << endl;
}
```

```cpp
for (auto it = vec.begin(); it < vec.end(); it++) {
    cout << *it << endl;
}
```
Range “for” statements [C++11]

Syntactic sugar that emulates Java’s “foreach”

works with any sequence-y type

strings, initializer lists, arrays with an explicit length defined, STL containers that support iterators

```cpp
// Prints out a string, one character per line

std::string str("hello");

for (auto c : str) {
    std::cout << c << std::endl;
}
```
Combining auto with range for

see vectoriterator_2011.cc
STL algorithms

A set of functions to be used on ranges of elements

range: any sequence that can be accessed through iterators or pointers, like arrays or some of the containers

algorithms operate directly on values using assignment or copy constructors, rather than modifying container structure

some do not modify elements

  find, count, for_each, min_element, binary_search, etc.

some do modify elements

  sort, transform, copy, swap, etc.
Example

see `vectoralgos.cc`
STL list

A generic doubly-linked list

- elements are *not* stored in contiguous memory locations
- does not support random access (cannot do list[5])
- some operations are much more efficient than vectors
  - constant time insertion, deletion anywhere in list
  - can iterate forward or backwards
- has a built-in sort member function
  - no copies; manipulates list structure instead of element values

http://www.cplusplus.com/reference/stl/list/
Example

see listexample.cc
STL map

A key/value table, implemented as a tree

- elements stored in sorted order
  - key value must support less-than operator
- keys must be unique
  - multimap allows duplicate keys
- efficient lookup ($O(\log n)$) and insertion ($O(\log n)$)
Example

see mapexample.cc
New in C++ 11

unordered_map, unordered_set

and related classes: unordered_multimap, unordered_multiset

average case for key access is $O(1)$

But range iterators can be less efficient than ordered map/set

See C++ Primer, online references for details
Exercise 1

Take one of the books from HW2’s test_tree, and:

- read in the book, split it into words (you can use your HW2)

for each word, insert the word into an STL map

  the key is the word, the value is an integer

  the value should keep track of how many times you’ve seen the word, so each time you encounter the word, increment its map element

  thus, build a histogram of word count

print out the histogram in order, sorted by word count

bonus: plot the histogram on a log/log scale (use excel, gnuplot, ...)

  xaxis: log(word number), y-axis: log(word count)
Exercise 2

Using the Tracer.cc/.h file from lecture:

construct a vector of lists of Tracers

i.e., a vector container, each element is a list of Tracers

observe how many copies happen. :)  

use the “sort” algorithm to sort the vector

use the “list.sort( )” function to sort each list
See you on Wednesday!
