Local bindings

There are 3 forms of local bindings with different semantics:

- `let`  
- `let*`  
- `letrec`

Also, in function bodies, a sequence of definitions is equivalent to `letrec`.

But at top-level redefinition is assignment!

This makes it ghastly hard to encapsulate code, but in practice:

- people assume non-malicious clients  
- implementations provide access to “real primitives”

For your homework, assume top-level definitions are immutable.

Delayed Evaluation

For each language construct, there are rules governing when subexpressions get evaluated. In ML, Scheme, and Java:

- function arguments are “eager” (*call-by-value*)  
- conditional branches are not

We could define a language in which function arguments were not evaluated before call, but instead at each use of argument in body. (*call-by-name*)

- Sometimes faster: `(lambda (x) 3)`  
- Sometimes slower: `(lambda (x) (+ x x))`  
- Equivalent if function argument has no effects/non-termination
Thunks

One (among several) meanings of “thunk” is just a function taking no arguments, which works great for delaying evaluation.

- Instead of passing a value directly, pass a thunk (function) which yields the value when it is called

If thunks are lightweight enough syntactically, why not make if eager? (Smalltalk does this!)
