CSE 341: 
Programming Languages

Hal Perkins
Spring 2011
Lecture 1— Course Introduction
Welcome!

We have 10 weeks to learn different paradigms and fundamental concepts of programming languages.

With diligence, patience, and an open mind, this course makes you a much better programmer (in languages we won’t use).

Today in class:

- Course mechanics
- (A rain-check on motivation)
- Dive into ML (homework 1 due end of next week — out shortly)

In the next day or so:

- Email homework 0 (worth 0 points) to me

http://www.cs.washington.edu/education/courses/cse341/11sp
Who and What

• 3 class meetings (slides, code, and questions)
  – Material on-line (subject to change), but take notes.
  – Grossman’s “essay versions” of lectures from Sp08 available.

• 1 section
  – Essential material on tools, style, examples, language-features, ...

• Office hours (course staff)
  – Use them
Textbooks

Texts are good, but take a fairly different approach to explaining things:

• That’s a good thing, for when my explanation doesn’t make sense.
• But don’t be surprised when I essentially ignore the texts.
• Ask questions about coverage, etc.
• Some but not all of you will do fine without using the texts.
• Do not cover the key concepts much if at all.
Homeworks

- Approximately weekly: with exams, 7 total
- Doing the homework involves:
  1. Understanding the concepts being addressed
  2. Writing code demonstrating understanding of the concepts
  3. Testing your code to ensure you understand
  4. “Playing around” with variations, incorrect answers, etc.

You turn in only (2), but focusing on (2) makes the homework harder

Challenge Problems: Low points/difficulty ratio

Assignments will be done individually.
Academic Integrity

Read every word of the course policy very carefully.

Always explain any unconventional action on your part.

Promoting and enforcing academic integrity has been a personal focus of mine for many years now:

- I trust you completely
- I have no sympathy for trust violations, nor should you

Honest work is the most important feature of a university.
Exams

- Midterm: Wednesday 27 April, in class (likely, but still tentative)
- Final: Thursday 9 June, 8:30–10:20

Same concepts, but very different format from homework.

- More conceptual (but write code too)
- Will post old exams
Now where were we?

Programming languages:

- Essential concepts relevant in any language
- Specific examples “in natural setting” using ML, Scheme, and Ruby (where a concept most “shines”)
- Focus on “functional languages” because they are simpler, very powerful, and teach good practices
  - Often a great way to think, even if “stuck” in Java or C
  - Languages/concepts increasingly important to the “real world”

First half of course uses ML:

- Gives us time to build knowledge before “starting over”
- But need to get comfortable with the basics as soon as possible
- “Let go of Java” for now (we will return to it)
A strange environment

The ML part of the course uses:

- The emacs editor
- A read-eval-print loop for evaluating programs
- Available on Windows and UNIX in the lab, and remotely via UNIX
- Also easy to install on personal machines (help each other out on the discussion board)

We have prepared “getting started” materials, but leave plenty of time for the content of homework 1.

- Read the materials
- Then ask questions fast (wasted hours are wasted hours)

Adjusting to new environments is a “CS life skill”
Before we dive in, part 1

We’ll return to the course goals and “why learn something other than C/C++/Java/Perl” at the end of next week.

(There are many great reasons, too important for the first day.)
ML, from the beginning

- A program is a sequence of *bindings*
- One kind of binding is a *variable binding*

```plaintext
val x = e ; (semicolon optional in a file)
```

- A program is evaluated by evaluating the bindings in order
- A *variable binding* is evaluated by:
  - Evaluating the expression in the environment created by the previous bindings. This produces a *value*.
  - Extending the (top-level) environment to bind the variable to the value.

Much easier to understand with an example...
That was a lot at once

- Values so far: integers, true, false, ()
- Non-value expressions so far: addition, subtraction, less than, conditionals
- Types: every expression has a type. So far, int, bool, unit
- The read-eval-print loop:
  - Enter a sequence of bindings. For each, it tells you the value and type of the new binding
  - If you just enter e;, then that is the same as val it = e;
  - use "foo.sml" enters the bindings from a file, and then binds it to (), which has type unit
  - Expressions that don’t type-check lead to (bad) error messages and no change to the environment
Parts worth repeating

Our very simple program demonstrates many critical language concepts:

• Expressions have a *syntax* (written form)
  – E.g.: A constant integer is written as a digit-sequence
  – E.g.: Addition expression is written $e_1 + e_2$

• Expressions *have types* given their context
  – E.g.: In any context, an integer has type `int`
  – E.g.: If $e_1$ and $e_2$ have type `int` in the current context, then $e_1 + e_2$ has type `int`

• Expressions *evaluate to values* given their environment
  – E.g.: In any environment, an integer evaluates to itself
  – E.g.: If $e_1$ and $e_2$ evaluate to $c_1$ and $c_2$ in the current environment, then $e_1 + e_2$ evaluates to the sum of $c_1$ and $c_2$
More expression forms

What are the syntax-rules, typing-rules, and evaluation-rules for:

- variables
- less-than comparisons
- conditional expressions
Lots more to do

We have many more types, expression forms, and binding forms to learn before we can write “anything interesting”.

Must develop resilience to mistakes and bad messages. Example gotcha: \( x = 7 \) instead of \( \text{val } x = 7 \).

For homework 1: functions, pairs, conditionals, lists, options, and local bindings (earlier problems require less)

But there are some things we will \textit{not} add:

- mutation (a.k.a. assignment): changing the value of an environment binding
  - make a new binding instead

- statements: expressions will do just fine, thank you

- loop-constructs: recursive functions are more powerful
What is a programming language?

Here are separable concepts for defining and learning a language:

- syntax: how do you write the various parts of the language?
- semantics: what do programs mean? (One way to answer: what are the evaluation rules?)
- idioms: how do you typically use the language to express computations?
- libraries: does the language provide “standard” facilities such as file-access, hashtables, etc.? How?
- tools: what is available for manipulating programs in the language? (e.g., compiler, debugger, REP-loop)
