This lecture

Three mostly separate topics

- Flexible arrays, ranges, and hashes [actually covered in section]
- Ruby’s approach to almost-closures (blocks) and closures (Procs)
  - [partially discussed in section as well]
  - Convenient to use; unusual approach
  - Used throughout large standard library
    - Explicit loops rare
    - Instead of a loop, go find a useful iterator
- Subclasses, inheritance, and overriding
  - The essence of OOP, now in a more dynamic language

Ruby Arrays

- Lots of special syntax and many provided methods for the Array class
- Can hold any number of other objects, indexed by number
  - Get via \( a[i] \)
  - Set via \( a[i] = e \)
- Compared to arrays in many other languages
  - More flexible and dynamic
  - Fewer operations are errors
  - Less efficient
- “The standard collection” (like lists were in ML and Racket)

Using Arrays

- See many examples, some demonstrated here
- Consult the documentation/tutorials
  - If seems sensible and general, probably a method for it
- Arrays make good tuples, lists, stacks, queues, sets, …
- Iterating over arrays typically done with methods taking blocks
  - Next topic…

Blocks

Blocks are probably Ruby’s strangest feature compared to other PLs

But almost just closures

- Normal: easy way to pass anonymous functions to methods for all the usual reasons
- Normal: Blocks can take 0 or more arguments
- Normal: Blocks use lexical scope: block body uses environment where block was defined

Examples:

```
3.times { puts "hi" }
[4,6,8].each { puts "hi" }
i = 7
[4,6,8].each {|x| if i > x then puts (x+1) end }
```

Some strange things

- Can pass 0 or 1 block with any message
  - Callee might ignore it
  - Callee might give an error if you do not send one
  - Callee might do different things if you do/don’t send one
    - Also number-of-block-arguments can matter
- Just put the block “next to” the “other” arguments (if any)
  - Syntax: \{e\}, \{x\} e, \{x,y\} e, etc. (plus variations)
    - Can also replace \( \) with do and end
      - Often preferred for blocks > 1 line
Blocks everywhere

- Rampant use of great block-taking methods in standard library
- Ruby has loops but very rarely used
  - Can write `(0..i).each { |j| e}`, but often better options
- Examples (consult documentation for many more)

```
blocks = Array.new(5) { |i| 4*i + 1 }
b.each { puts "hi" }
b.each { |x| puts x * 2 }  # synonym: collect
b.any? { |x| x > 7 }
b.all? { |x| x > 7 }
b.inject(0) { |acc, elt| acc + elt }
b.select { |x| x > 7 }  # synonym: filter
```

More strangeness

- Callee does not give a name to the (potential) block argument
- Instead, just calls it with `yield` or `yield(args)`
  - Silly example:
    ```ruby
def silly a
  (yield a) + (yield 42)
end
```

- Can ask `block_given?` but often just assume a block is given
  or that a block's presence is implied by other arguments

Blocks are “second-class”

All a method can do with a block is `yield` to it
- Cannot return it, store it in an object (e.g., for a callback), ...
- But can also turn blocks into real closures
- Closures are instances of class `Proc`
  - Called with method `call`

This is Ruby, so there are several ways to make `Proc` objects:
- One way: method `lambda` of `Object` takes a block and returns the corresponding `Proc`

```
a = [3, 5, 7, 9]
b = a.map { |x| x + 1 }
i = b.count { |x| x > 6 }
```

Example

- Blocks are fine for applying to array elements
  ```ruby
  b = a.map { |x| x + 1 }
i = b.count { |x| x > 6 }
  ```

- But for an array of closures, need `Proc` objects
  - More common use is callbacks
    ```ruby
c = a.map { |x| lambda { |y| x >= y} }
c[2].call 17
j = c.count { |x| x.call(5) }
```

Moral

- First-class (“can be passed/stored anywhere”) makes closures more powerful than blocks
- But blocks are (a little) more convenient and cover most uses
- This helps us understand what first-class means
- Language design question: When is convenience worth making something less general and powerful?

More collections

- **Hashes** like arrays but:
  - Keys can be anything; strings and symbols common
  - No natural ordering like numeric indices
  - Different syntax to make them
    Like a dynamic record with anything for field names
  - Often pass a hash rather than many arguments

- **Ranges** like arrays of contiguous numbers but:
  - More efficiently represented, so large ranges fine

Good style to:
- Use ranges when you can
- Use hashes when non-numeric keys better represent data
Similar methods

- Arrays, hashes, and ranges all have some methods other don’t
  - E.g., keys and values
- But also have many of the same methods, particularly iterators
  - Great for duck typing
  - Example

```ruby
def foo a
  a.count {|x| x*x < 50}
end
foo [3,5,7,9]
foo (3..9)
```

Once again separating “how to iterate” from “what to do”

Next major topic

- Subclasses, inheritance, and overriding
  - The essence of OOP
  - Not unlike you have seen in Java, but worth studying from PL perspective and in a more dynamic language

Subclassing

- A class definition has a superclass (Object if not specified)
  ```ruby
class ColorPoint < Point ...
  ```
- The superclass affects the class definition:
  - Class inherits all method definitions from superclass
  - But class can override method definitions as desired
- Unlike Java/C#/C++:
  - No such thing as “inheriting fields” since all objects create instance variables by assigning to them
  - Subclassing has nothing to do with a (non-existent) type system: can still (try to) call any method on any object

Example (to be continued)

```ruby
class Point
  attr_accessor :x, :y
  def initialize(x,y)
    @x = x
    @y = y
  end
  def distFromOrigin
    # direct field access
    Math.sqrt(@x*@x + @y*@y)
  end
  end

class ColorPoint < Point
  attr_accessor :color
  def initialize(x,y,c)
    super(x,y)
    @color = c
  end
end
```

Example continued

- Consider alternatives to:
  ```ruby
  class ColorPoint < Point
    attr_accessor :color
    def initialize(x,y,c)
      super(x,y)
      @color = c
    end
  end
  ```
- Here subclassing is a good choice, but programmers often overuse subclassing in OOP languages

An object has a class

- Using these methods is usually non-OOP style
  - Disallows other things that “act like a duck”
  - Nonetheless semantics is that an instance of ColorPoint is a Point but is not an “instance of” Point
  - [Java note: instanceof is like Ruby’s is_a?]

```ruby
p = Point.new(0,0)
cp = ColorPoint.new(0,0,"red")
p.class           # Point
p.class.superclass # Object
cp.class          # ColorPoint
cp.class.superclass # Point
cp.class.superclass.superclass # Object
cp.is_a? Point    # true
cp.instance_of? Point # false
cp.is_a? ColorPoint # true
cp.instance_of? ColorPoint # true
```
**Why subclass**

- Instead of creating `ColorPoint`, could add methods to `Point`
  - That could mess up other users and subclassers of `Point`

```ruby
class Point
  attr_accessor :color
  def initialize(x,y,c="clear")
    @x = x
    @y = y
    @color = c
  end
end
```

**Why subclass**

- Instead of subclassing `Point`, could copy/paste the methods
  - Means the same thing if you don’t use methods like `is_a?` and `superclass`, but of course code reuse is nice

```ruby
class ColorPoint
  attr_accessor :x, :y, :color
  def initialize(x,y,c="clear")
  end
  def distFromOrigin
    Math.sqrt(@x*@x + @y*@y)
  end
  def distFromOrigin2
    Math.sqrt(x*x + y*y)
  end
end
```

**Why subclass**

- Instead of subclassing `Point`, could use a `Point` instance variable
  - Define methods to send same message to the `Point`
  - Often OOP programmers overuse subclassing
  - But for `ColorPoint`, subclassing makes sense: less work and can use a `ColorPoint` wherever code expects a `Point`

```ruby
class ColorPoint
  attr_accessor :color
  def initialize(x,y,c="clear")
    @pt = Point.new(x,y)
    @color = c
  end
  def x
    @pt.x
  end
  # similar "forwarding" methods for y, x=, y=
end
```

**Overriding**

- `ThreeDPoint` is more interesting than `ColorPoint` because it overrides `distFromOrigin` and `distFromOrigin2`
  - Gets code reuse, but highly disputable if it is appropriate to say a `ThreeDPoint` “is a” `Point`
  - Still just avoiding copy/paste

```ruby
class ThreeDPoint < Point
  def initialize(x,y,z)
    super(x,y)
    @z = z
  end
  def distFromOrigin # distFromOrigin2 similar
    d = super
    Math.sqrt(d*d + @z*@z)
  end
end
```

**So far…**

- With examples so far, objects are not so different from closures
  - Multiple methods rather than just “call me”
  - Explicit instance variables rather than environment where function is defined
  - Inheritance avoids helper functions or code copying
  - “Simple” overriding just replaces methods

- But there is one big difference:

  *Overriding can make a method defined in the superclass call a method in the subclass*

  *The essential difference of OOP, studied carefully next lecture*

**Example: Equivalent except constructor**

```ruby
class PolarPoint < Point
  def initialize(r,theta)
    @r = r
    @theta = theta
  end
  def x
    @r * Math.cos(@theta)
  end
  def y
    @r * Math.sin(@theta)
  end
  def distFromOrigin
    @r
  end
end
```

- Also need to define `x=` and `y=` (see code file)
  - Key punchline: `distFromOrigin2`, defined in `Point`, “already works”
    ```ruby
    def distFromOrigin2
      Math.sqrt(x*x+y*y)
    end
    ```
    - Why: “calls to self are resolved in terms of the object’s class”
