CSE341: Programming Languages

Lecture 4
Records, Datatypes, Case Expressions

Dan Grossman
Spring 2017
Five different things

1. Syntax: How do you write language constructs?
3. Idioms: What are typical patterns for using language features to express your computation?
4. Libraries: What facilities does the language (or a well-known project) provide “standard”? (E.g., file access, data structures)
5. Tools: What do language implementations provide to make your job easier? (E.g., REPL, debugger, code formatter, …)
   - Not actually part of the language

These are 5 separate issues
   - In practice, all are essential for good programmers
   - Many people confuse them, but shouldn’t
Our Focus

This course focuses on semantics and idioms

- Syntax is usually uninteresting
  - A fact to learn, like “The American Civil War ended in 1865”
  - People obsess over subjective preferences

- Libraries and tools crucial, but often learn new ones “on the job”
  - We are learning semantics and how to use that knowledge to understand all software and employ appropriate idioms
  - By avoiding most libraries/tools, our languages may look “silly” but so would any language used this way
How to build bigger types

- Already know:
  - Have various base types like `int` `bool` `unit` `char`
  - Ways to build (nested) compound types: tuples, lists, options

- Coming soon: more ways to build compound types

- First: 3 most important type building blocks in any language
  - “Each of”: A `t` value contains values of each of `t1` `t2` ... `tn`
  - “One of”: A `t` value contains values of one of `t1` `t2` ... `tn`
  - “Self reference”: A `t` value can refer to other `t` values

Remarkable: A lot of data can be described with just these building blocks

Note: These are not the common names for these concepts
Examples

• Tuples build each-of types
  – `int * bool` contains an `int` and a `bool`

• Options build one-of types
  – `int option` contains an `int` or it contains no data

• Lists use all three building blocks
  – `int list` contains an `int` and another `int list` or it contains no data

• And of course we can nest compound types
  – `((int * int) option * (int list list)) option`
Rest of this Lecture

- Another way to build each-of types in ML
  - *Records*: have named *fields*
  - Connection to tuples and idea of *syntactic sugar*

- A way to build and use our own one-of types in ML
  - For example, a type that contains an *int* or a *string*
  - Will lead to *pattern-matching*, one of ML’s coolest and strangest-to-Java-programmers features

- Later in course: How OOP does one-of types
  - Key contrast with procedural and functional programming
Records

Record values have fields (any name) holding values

\{f1 = v1, ..., fn = vn\}

Record types have fields (and name) holding types

\{f1 : t1, ..., fn : tn\}

The order of fields in a record value or type never matters
– REPL alphabetizes fields just for consistency

Building records:

\{f1 = e1, ..., fn = en\}

Accessing components:

#myfieldname e

(Evaluation rules and type-checking as expected)
Example

{\text{name} = "Matai", \text{id} = 4 - 3}

Evaluates to

{\text{id} = 1, \text{name} = "Matai"}

And has type

{\text{id} : \text{int}, \text{name} : \text{string}}

If some expression such as a variable \( x \) has this type, then get fields with:

\#id x \quad \#name x

Note we did not have to declare any record types

– The same program could also make a

\{\text{id}=\text{true},\text{ego}=\text{false}\} \quad \text{of type} \quad \{\text{id} : \text{bool}, \text{ego} : \text{bool}\}
By name vs. by position

• Little difference between \((4, 7, 9)\) and \(\{f=4, g=7, h=9\}\)
  – Tuples a little shorter
  – Records a little easier to remember “what is where”
  – Generally a matter of taste, but for many (6? 8? 12?) fields, a record is usually a better choice

• A common decision for a construct’s syntax is whether to refer to things by position (as in tuples) or by some (field) name (as with records)
  – A common hybrid is like with Java method arguments (and ML functions as used so far):
    • Caller uses position
    • Callee uses variables
    • Could totally do it differently; some languages have
The truth about tuples

Previous lecture gave tuples syntax, type-checking rules, and evaluation rules

But we could have done this instead:
- Tuple syntax is just a different way to write certain records
  - \((e_1, \ldots, e_n)\) is another way of writing \(\{1=e_1, \ldots, n=e_n\}\)
  - \(t_1 \times \ldots \times t_n\) is another way of writing \(\{1:t_1, \ldots, n:t_n\}\)
- In other words, records with field names 1, 2, ...

In fact, this is how ML actually defines tuples
- Other than special syntax in programs and printing, they don’t exist
- You really can write \(\{1=4, 2=7, 3=9\}\), but it’s bad style
Syntactic sugar

“Tuples are just syntactic sugar for records with fields named 1, 2, … n”

- **Syntactic**: Can describe the semantics entirely by the corresponding record syntax
- **Sugar**: They make the language sweeter 😊

Will see many more examples of syntactic sugar
- They simplify *understanding* the language
- They simplify *implementing* the language

Why? Because there are fewer semantics to worry about even though we have the syntactic convenience of tuples

Another example we saw: **andalso** and **orelse** vs. **if then else**
Datatype bindings

A “strange” (?) and totally awesome (!) way to make one-of types:

– A datatype binding

```
datatype mytype = TwoInts of int * int
                | Str of string
                | Pizza
```

• Adds a new type `mytype` to the environment
• Adds constructors to the environment: `TwoInts`, `Str`, and `Pizza`
• A constructor is (among other things), a function that makes values of the new type (or is a value of the new type):
  
  – `TwoInts : int * int -> mytype`
  – `Str : string -> mytype`
  – `Pizza : mytype`
The values we make

```
datatype mytype = TwoInts of int * int
    | Str of string
    | Pizza
```

- Any value of type `mytype` is made from one of the constructors
- The value contains:
  - A “tag” for “which constructor” (e.g., `TwoInts`)
  - The corresponding data (e.g., `(7, 9)`)
- Examples:
  - `TwoInts(3+4, 5+4)` evaluates to `TwoInts(7, 9)`
  - `Str(if true then "hi" else "bye")` evaluates to `Str("hi")`
  - `Pizza` is a value
Using them

So we know how to build datatype values; need to access them.

There are two aspects to accessing a datatype value:
1. Check what variant it is (what constructor made it)
2. Extract the data (if that variant has any)

Notice how our other one-of types used functions for this:
• `null` and `isSome` check variants
• `hd`, `tl`, and `valOf` extract data (raise exception on wrong variant)

ML could have done the same for datatype bindings
  – For example, functions like “isStr” and “getStrData”
  – Instead it did something better
Case

ML combines the two aspects of accessing a one-of value with a case expression and pattern-matching

– Pattern-matching much more general/powerful (Lecture 5)

Example:

```haskell
fun f x = (* f has type mytype -> int *)
      case x of
        Pizza => 3
      | TwoInts(i1,i2) => i1+i2
      | Str s => String.size s
```

• A multi-branch conditional to pick branch based on variant
• Extracts data and binds to variables local to that branch
• Type-checking: all branches must have same type
• Evaluation: evaluate between case … of and the right branch
Patterns

In general the syntax is:

```
case e0 of
  p1 => e1
  | p2 => e2
  ...
  | pn => en
```

For today, each pattern is a constructor name followed by the right number of variables (i.e., \(C\) or \(C\ x\) or \(C\ (x, y)\) or …)

- Syntactically most patterns (all today) look like expressions
- But patterns are not expressions
  - We do not evaluate them
  - We see if the result of \(e0\) matches them
Why this way is better

0. You can use pattern-matching to write your own testing and data-extractions functions if you must
   – But do not do that on your homework

1. You cannot forget a case (inexhaustive pattern-match warning)
2. You cannot duplicate a case (a type-checking error)
3. You will not forget to test the variant correctly and get an exception (like `hd []`)
4. Pattern-matching can be generalized and made more powerful, leading to elegant and concise code
