fork: Creating New Processes

- `int fork(void)`
  - creates a new process (child process) that is identical to the calling process (parent process)
  - returns 0 to the child process
  - returns child’s process ID (`pid`) to the parent process

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

- Fork is interesting (and often confusing) because it is called *once* but returns *twice*
Understanding fork

Process n

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```
Understanding fork

Process $n$

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

Child Process $m$

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

$\text{pid} = m$
Understanding fork

**Process n**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**Child Process m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```
Understanding fork

**Process n**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**Child Process m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**pid = m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**pid = 0**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```
Understanding fork

**Process n**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**Child Process m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**Child Process m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

**Child Process m**

```c
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

Which one is first?
Fork Example #1

- Parent and child both run same code
  - Distinguish parent from child by return value from `fork`

- Start with same state, but each has private copy
  - Including shared output file descriptor
  - Relative ordering of their print statements undefined

```c
void fork1()
{
    int x = 1;
    pid_t pid = fork();
    if (pid == 0) {
        printf("Child has x = %d\n", ++x);
    } else {
        printf("Parent has x = %d\n", --x);
    }
    printf("Bye from process %d with x = %d\n", getpid(), x);
}
```
Fork Example #2

- Both parent and child can continue forking

```c
void fork2()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("Bye\n");
}
```
Fork Example #2

- Both parent and child can continue forking

```c
void fork2()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("Bye\n");
}
```
Fork Example #3

- Both parent and child can continue forking

```c
void fork3()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("L2\n");
    fork();
    printf("Bye\n");
}
```
Fork Example #3

- Both parent and child can continue forking

```c
void fork3()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("L2\n");
    fork();
    printf("Bye\n");
}
```
Fork Example #4

- Both parent and child can continue forking

```c
void fork4()
{
    printf("L0\n");
    if (fork() != 0) {
        printf("L1\n");
        if (fork() != 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```
Fork Example #4

- Both parent and child can continue forking

```c
void fork4()
{
    printf("L0\n");
    if (fork() != 0) {
        printf("L1\n");
        if (fork() != 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```
Fork Example #4

- Both parent and child can continue forking

```c
void fork5()
{
    printf("L0\n");
    if (fork() == 0) {
        printf("L1\n");
        if (fork() == 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```
Fork Example #4

- Both parent and child can continue forking

```c
void fork5()
{
    printf("L0\n");
    if (fork() == 0) {
        printf("L1\n");
        if (fork() == 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```
**exit: Ending a process**

- **void exit**
  - 
  - status)

  exits a process

- Normally, return with status 0

```c
void cleanup(void) {
    printf("cleaning up\n");
}

void fork6() {
    atexit(cleanup);
    fork();
    exit(0);
}
```
Zombies

- **Idea**
  - When process terminates, still consumes system resources
    - Various tables maintained by OS
  - Called a “zombie”
    - That is, a living corpse, half alive and half dead

- **Reaping**
  - Performed by parent on terminated child (*horror movie!*)
  - Parent is given exit status information
  - Kernel discards process

- **What if parent doesn’t reap?**
  - If any parent terminates without reaping a child, then child will be reaped by *init* process
  - So, only need explicit reaping in long-running processes
    - e.g., shells and servers
Zombie Example

void fork7()
{
  if (fork() == 0) {
    /* Child */
    printf("Terminating Child, PID = %d\n", getpid());
    exit(0);
  } else {
    printf("Running Parent, PID = %d\n", getpid());
    while (1)
      ; /* Infinite loop */
  }
}

- **ps** shows child process as “defunct”
- Killing parent allows child to be reaped by **init**
Non-terminating Child Example

```c
void fork8()
{
    if (fork() == 0) {
        /* Child */
        printf("Running Child, PID = %d\n", getpid());
        while (1)
            ; /* Infinite loop */
    } else {
        printf("Terminating Parent, PID = %d\n", getpid());
        exit(0);
    }
}
```

- Child process still active even though parent has terminated
- Must kill explicitly, or else will keep running indefinitely
Synchronization!
wait: Synchronizing with Children

```c
int wait(int *child_status)

  suspends current process until one of its children terminates
  return value is the pid of the child process that terminated
  if child_status != NULL, then the object it points to will be set
to a status indicating why the child process terminated
```
wait: Synchronizing with Children

```c
void fork9() {
    int child_status;

    if (fork() == 0) {
        printf("HC: hello from child\n");
    }
    else {
        printf("HP: hello from parent\n");
        wait(&child_status);
        printf("CT: child has terminated\n");
    }
    printf("Bye\n");
    exit();
}
```
wait() Example

- If multiple children completed, will take in arbitrary order
- Can use macros WIFEXITED and WEXITSTATUS to get information about exit status

```c
void fork10()
{
    pid_t pid[N];
    int i;
    int child_status;
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            exit(100+i); /* Child */
    for (i = 0; i < N; i++) {
        pid_t wpid = wait(&child_status);
        if (WIFEXITED(child_status))
            printf("Child %d terminated with exit status %d\n", wpid, WEXITSTATUS(child_status));
        else
            printf("Child %d terminated abnormally\n", wpid);
    }
}
```
waitpid(): Waiting for a Specific Process

- **waitpid(pid, &status, options)**
  - suspends current process until specific process terminates
  - various options (that we won’t talk about)

```c
void fork11()
{
    pid_t pid[N];
    int i;
    int child_status;
    for (i = 0; i < N; i++)
        if ((pid[i] = fork()) == 0)
            exit(100+i); /* Child */
    for (i = 0; i < N; i++) {
        pid_t wpid = waitpid(pid[i], &child_status, 0);
        if (WIFEXITED(child_status))
            printf("Child %d terminated with exit status %d\n", wpid, WEXITSTATUS(child_status));
        else
            printf("Child %d terminated abnormally\n", wpid);
    }
}```
**execve: Loading and Running Programs**

- **int execve(**
  - char *filename,
  - char *argv[],
  - char *envp
  )
- **Loads and runs**
  - Executable **filename**
  - With argument list **argv**
  - And environment variable list **envp**
- **Does not return (unless error)**
- **Overwrites process, keeps pid**
- **Environment variables:**
  - “name=value” strings
**execve: Example**

```
envp[n] = NULL
envp[n-1] → "PWD=/homes/iws/luisceze"
...
envp[0] → "USER=luisceze"

argv[argc] = NULL
argv[argc-1] → "/usr/include"
...
argv[0] → "ls"
```
Summary

- **Exceptions**
  - Events that require non-standard control flow
  - Generated externally (interrupts) or internally (traps and faults)

- **Processes**
  - At any given time, system has multiple active processes
  - Only one can execute at a time, however,
  - Each process appears to have total control of the processor + has a private memory space
Summary (cont’d)

- **Spawning processes**
  - Call to `fork`
  - One call, two returns

- **Process completion**
  - Call `exit`
  - One call, no return

- **Reaping and waiting for Processes**
  - Call `wait` or `waitpid`

- **Loading and running Programs**
  - Call `exec1` (or variant)
  - One call, (normally) no return
