The AVL Tree Data Structure

Structural properties
1. Binary tree property
2. Balance property: balance of every node is between -1 and 1
Result: Worst-case depth is $O(\log n)$

Ordering property
– Same as for BST

The shallowness bound
Let $S(h)$ = the minimum number of nodes in an AVL tree of height $h$
– If we can prove that $S(h)$ grows exponentially in $h$, then a tree with $n$ nodes has a logarithmic height

• Step 1: Define $S(h)$ inductively using AVL property
  – $S(-1)=0$, $S(0)=1$, $S(1)=2$
  – For $h \geq 1$, $S(h) = 1+S(h-1)+S(h-2)$

• Step 2: Show this recurrence grows really fast
  – Can prove for all $h$, $S(h) > \phi^h - 1$ where
    $\phi$ is the golden ratio, $(1+\sqrt{5})/2$, about 1.62
  – Growing faster than $1.6^h$ is “plenty exponential”
    • It does not grow faster than $2^h$

Before we prove it
• Good intuition from plots comparing:
  – $S(h)$ computed directly from the definition
  – $(1+\sqrt{5})/2)^h$
• $S(h)$ is always bigger, up to trees with huge numbers of nodes
  – Graphs aren’t proofs, so let’s prove it
The Golden Ratio

\[ \phi = \frac{1 + \sqrt{5}}{2} \approx 1.62 \]

This is a special number

- Aside: Since the Renaissance, many artists and architects have proportioned their work (e.g., length:height) to approximate the golden ratio: if \( \frac{a+b}{a} = \frac{a}{b} \), then \( a/b = \phi \)

- We will need one special arithmetic fact about \( \phi \): 
  \[ \phi^2 = \frac{(1 + 5^{1/2})^2}{4} = \frac{(1 + 2 \cdot 5^{1/2} + 5)}{4} = \frac{(6 + 2 \cdot 5^{1/2})}{4} = \frac{1 + (1 + 5^{1/2})}{2} = 1 + \phi \]

Good news

Proof means that if we have an AVL tree, then find is \( O(\log n) \)
- Recall logarithms of different bases \( > 1 \) differ by only a constant factor

But as we insert and delete elements, we need to:
1. Track balance
2. Detect imbalance
3. Restore balance

Is this AVL tree balanced?
How about after insert(30)?

AVL tree operations

- AVL find:
  - Same as BST find

- AVL insert:
  - First BST insert, then check balance and potentially “fix” the AVL tree
  - Four different imbalance cases

- AVL delete:
  - The “easy way” is lazy deletion
  - Otherwise, do the deletion and then have several imbalance cases (we will likely skip this but post slides for those interested)

The proof

\[ S(-1)=0, \ S(0)=1, \ S(1)=2 \]

For \( h \geq 1 \), \( S(h) = 1 + S(h-1) + S(h-2) \)

Theorem: For all \( h \geq 0 \), \( S(h) > \phi^h - 1 \)

Proof: By induction on \( h \)

Base cases:
\[ S(0) = 1 > \phi^0 - 1 = 0 \]
\[ S(1) = 2 > \phi^1 - 1 \approx 0.62 \]

Inductive case (\( k > 1 \)):
Show \( S(k+1) > \phi^{k+1} - 1 \) assuming \( S(k) > \phi^k - 1 \) and \( S(k-1) > \phi^{k-1} - 1 \)

\[ S(k+1) = 1 + S(k) + S(k-1) \quad \text{by definition of } S \]
\[ > 1 + \phi^k - 1 + \phi^{k-1} - 1 \quad \text{by induction} \]
\[ = \phi^k + \phi^{k-1} - 1 \quad \text{by arithmetic (1-1=0)} \]
\[ = \phi^{k+1} (\phi + 1) - 1 \quad \text{by arithmetic (factor } \phi^{k+1}) \]
\[ = \phi^{k+1} \phi^2 - 1 \quad \text{by special property of } \phi \]
\[ = \phi^{k+1} - 1 \quad \text{by arithmetic (add exponents)} \]

An AVL Tree

Insert: detect potential imbalance

1. Insert the new node as in a BST (a new leaf)
2. For each node on the path from the root to the new leaf, the insertion may (or may not) have changed the node’s height
3. So after recursive insertion in a subtree, detect height imbalance and perform a rotation to restore balance at that node

All the action is in defining the correct rotations to restore balance

Fact that an implementation can ignore:
- There must be a deepest element that is unbalanced after the insert (all descendants still balanced)
- After rebalancing this deepest node, every node is balanced
- So at most one node needs to be rebalanced
Case #1: Example

Insert(6)
Insert(3)
Insert(1)

Third insertion violates balance property
- happens to be at the root

What is the only way to fix this?

The example generalized

- Node imbalanced due to insertion somewhere in left-left grandchild increasing height
  - 1 of 4 possible imbalance causes (other three coming)
  - First we did the insertion, which would make a imbalanced

Another example: insert(16)

Fall 2013 13 CSE373: Data Structures & Algorithms

Fall 2013 14 CSE373: Data Structures & Algorithms

Fix: Apply “Single Rotation”

- Single rotation: The basic operation we’ll use to rebalance
  - Move child of unbalanced node into parent position
  - Parent becomes the “other” child (always okay in a BST!)
  - Other subtrees move in only way BST allows (next slide)

AVL Property violated here

Intuition: 3 must become root
new-parent-height = old-parent-height-before-insert

The general left-left case

- Node imbalanced due to insertion somewhere in left-left grandchild
  - 1 of 4 possible imbalance causes (other three coming)
  - So we rotate at a, using BST facts: X < b < Y < a < Z

Another example: insert(16)

Fall 2013 15 CSE373: Data Structures & Algorithms

Fall 2013 16 CSE373: Data Structures & Algorithms

Fall 2013 18 CSE373: Data Structures & Algorithms
The general right-right case

- Mirror image to left-left case, so you rotate the other way
  - Exact same concept, but need different code

Two cases to go

Unfortunately, single rotations are not enough for insertions in the left-right subtree or the right-left subtree

Simple example: \texttt{insert(1), insert(6), insert(3)}
  - Second wrong idea: single rotation on the child of the unbalanced node

Sometimes two wrongs make a right

- First idea violated the BST property
- Second idea didn’t fix balance
- But if we do both single rotations, starting with the second, it works! (And not just for this example.)
- Double rotation:
  1. Rotate problematic child and grandchild
  2. Then rotate between self and new child

Comments

- Like in the left-left and right-right cases, the height of the subtree after rebalancing is the same as before the insert
  - So no ancestor in the tree will need rebalancing
- Does not have to be implemented as two rotations; can just do:

Easier to remember than you may think:
Move a, b, X, U, V, and Z in the only legal positions for a BST
The last case: left-right

- Mirror image of right-left
  - Again, no new concepts, only new code to write

Insert, summarized

- Insert as in a BST
- Check back up path for imbalance, which will be 1 of 4 cases:
  - Node’s left-left grandchild is too tall
  - Node’s left-right grandchild is too tall
  - Node’s right-left grandchild is too tall
  - Node’s right-right grandchild is too tall
- Only one case occurs because tree was balanced before insert
- After the appropriate single or double rotation, the smallest-unbalanced subtree has the same height as before the insertion
  - So all ancestors are now balanced

Now efficiency

- Worst-case complexity of \textit{find}: \(O(\log n)\)
  - Tree is balanced
- Worst-case complexity of \textit{insert}: \(O(\log n)\)
  - Tree starts balanced
  - A rotation is \(O(1)\) and there’s an \(O(\log n)\) path to root
  - (Same complexity even without one-rotation-is-enough fact)
  - Tree ends balanced
- Worst-case complexity of \textit{buildTree}: \(O(n \log n)\)

Pros and Cons of AVL Trees

Arguments for AVL trees:
1. All operations logarithmic worst-case because trees are always balanced
2. Height balancing adds no more than a constant factor to the speed of \textit{insert} and \textit{delete}

Arguments against AVL trees:
1. Difficult to program & debug [but done once in a library!]
2. More space for height field
3. Asymptotically faster but rebalancing takes a little time
4. Most large searches are done in database-like systems on disk and use other structures (e.g., B-trees, a data structure in the text)
5. If \textit{amortized} (later, I promise) logarithmic time is enough, use splay trees (also in the text)
