Lecture 21 – Function Pointers and Objects in C
Function pointers

• “Pointers to code” are almost as useful as “pointers to data”. (But the syntax is painful in C.)
• (Somewhat silly) example:
  
  ```c
  void app_arr(int len, int * arr, int (*f)(int)) {
    for(int k = 0; k < len; k++)
      arr[k] = (*f)(arr[k]);
  }

  int twox(int i) { return 2*i; }
  int sqr(int i)    { return i*i; }
  void twoXarr(int len, int* arr) {app_arr(len,arr,&twox);}
  void sqr_arr(int len, int* arr) { app_arr(len,arr,&sqr); }
  ```
C function-pointer syntax

• C syntax: painful and confusing. Rough idea: The compiler “knows” what is code and what is a pointer to code, so you can write less than we did on the last slide:
  \[
  \text{arr}[k] = (*f)(\text{arr}[k]); \\
  \Rightarrow \text{arr}[k] = f(\text{arr}[k]); \\
  \text{app\_arr}(\text{len}, \text{arr}, \&\text{twoX}); \\
  \Rightarrow \text{app\_arr}(\text{len}, \text{arr}, \text{twoX});
  \]

• Examples: Compute integral with function (pointer) to integrate and bounds as parameters (int1.c, int2.c)
What is an object?

First Approximation

• An object consists of data and methods
  – Provides the correct (conceptual) model
  – Easy to explain

• But…
  – Doesn’t make engineering sense — we don’t want to replicate the (same) method bodies (function code) in every object
What is an object?

Second Approximation

• An object consists of data and pointers to methods
• The compiler adds an additional, implicit “this” parameter to every method holding a reference to the receiver object
  – Gives the method a way to refer to the instance variables of the correct receiver object
  – Actual method (function) code has no other connection to any particular object
• Avoids code duplication
• See BAccount1.c (C version of Baccount.cpp)

But . . .

• Still wastes space for pointers to every class function in every object, particularly if there is relatively little instance data, or if the class has a large number of methods
What is an object?

How it’s really done (C++, Java, et al):
• There is a single “virtual function” table (vtable) for each class containing pointers to the methods of that class.
  – This is static, constant class data – does not change during execution; initialized at load/startup time
• An object consists of data and a pointer to its class vtable
• Method calls are indirect through the vtable
• Each method still has an implicit this parameter that refers to the receiving object
• Avoids code duplication
• Avoids method pointer duplication
• Costs an indirect pointer lookup during each function call
• Example: BAccount2.c
Inheritance and overriding

Basic ideas:

• We have a vtable for every class and subclass
• The vtable for a subclass points to the correct methods — either ones belonging to the base class that are inherited, or ones belonging to the subclass (added or overriding)
• Key idea: The initial part of the vtable for a subclass points to the methods that are inherited or overridden from the base class in exactly the same order they appear in the base class vtable
  – So compiled code can find the correct method at the same offset in the vtable whether it is overridden or not
• Use casts as needed to adjust references up and down the inheritance chain
