

Jumping To Procedures

It beats jumping to conclusions

Multiply

- Multiply `mult` is an R-type instruction, but is complicated by the fact that the product of 2 32-bit numbers can be 64-bits long
- There is a special multiply result register

`mult $8,$10 # Go forth and multiply`

op	rs	rt	rd	shamt	funct
0	8	10	0	0	24
000000	01000	01010	000000	000000	011000

The result can be removed using **move from high, mfhi** to get the MSB's and **move from low, mflo**, to get the LSBs

Jumping

- The jr instruction has an R-type format and jumps to the address in the operand register

- jr is mostly used for procedure return

The address in the register is a true memory address, not PC-relative instruction address

The Long Jump

- The jump instruction j is a J-format instruction

© Larry Snyder, 2000. All rights reserved

Jump and Link

- The jump and link **jal** instruction is J-type
- It jumps to the address like **j**, but saves the address of the next instruction in **\$ra**

jal is used to call procedures, since saving the link allows the procedure to return to the point of the call

Register Usage

The assembler conventions on register usage

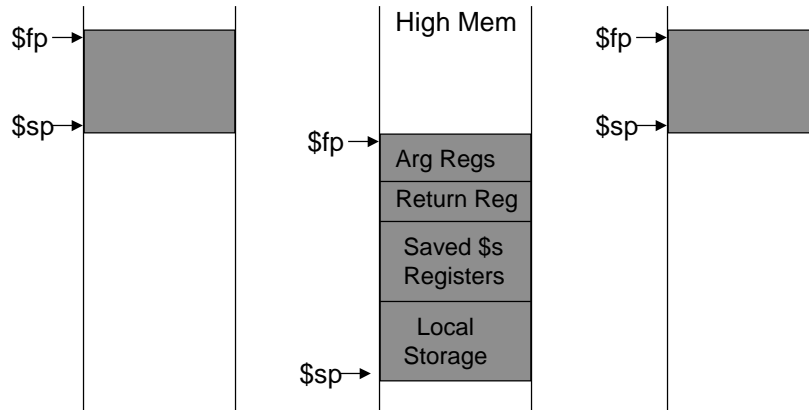

Name	Reg. No.	Usage	Preserved On Cal
\$zero	0	Constant value 0	N.A.
	1	Reserved for Assm	N.A.
\$v0-\$v1	2-3	Result registers	No
\$a0-\$a3	4-7	Arguments	Yes
\$t0-\$t7	8-15	Temporaries	No
\$s0-\$s7	16-23	Saved Locals	Yes
\$t8-\$t9	24-25	More temporaries	No
	26-27	Operating System	N.A.
\$gp	28	Global Pointer	Yes
\$sp	29	Stack Pointer	Yes
\$fp	30	Frame Pointer	Yes
\$ra	31	Return Address	Yes

See Appendix A-6 for more information

The Stack Allocation

The stack provides the dynamic storage for saving state during procedure calls
