Black/White-Box Testing

Reading:

*Software Testing: Principles and Practices*, Ch. 3-4 (Desikan, Ramesh)

slides created by Marty Stepp
http://www.cs.washington.edu/403/
• Should I test my own code, or should somebody else?
• Which code of my project should I test the most/least?
• Can I test all possible inputs to see whether something works?
• How do I know if I've tested well/enough?
• What constitutes a good or bad test case method?
• Is it good or bad if a test case fails?
• What if a test case itself has a bug in it?
JUnit exercise

Given a `Date` class with the following methods:

- `public Date(int year, int month, int day)`
- `public Date()` // today
- `public int getDay(), getMonth(), getYear()`
- `public void addDays(int days)` // advances by days
- `public int daysInMonth()`
- `public String dayOfWeek()` // e.g. "Sunday"
- `public boolean equals(Object o)`
- `public boolean isLeapYear()`
- `public void nextDay()` // advances by 1 day
- `public String toString()`

• Come up with unit tests to check the following:
  - That no `Date` object can ever get into an invalid state.
  - That the `addDays` method works properly.
    • It should be efficient enough to add 1,000,000 days in a call.
• Imagine that we'd like to add a method `subtractWeeks` to our Date class, that shifts this Date backward in time by the given number of weeks.

• Write code to test this method `before` it has been written.
  – This way, once we do implement the method, we'll know whether it works.
What is the difference between black- and white-box testing?

- **black-box** (procedural) **test**: Written without knowledge of how the class under test is implemented.
  - focuses on input/output of each component or call

- **white-box** (structural) **test**: Written with knowledge of the implementation of the code under test.
  - focuses on internal states of objects and code
  - focuses on trying to cover all code paths/statements
  - requires internal knowledge of the component to craft input
    - example: knowing that the internal data structure for a spreadsheet uses 256 rows/columns, test with 255 or 257
Black-box testing

- black-box is based on requirements and functionality, not code
- tester may have actually seen the code before ("gray box")
  - but doesn't look at it while constructing the tests
- often done from the end user or OO client's perspective
- emphasis on parameters, inputs/outputs (and their validity)
Types of black-box

- requirements based
- positive/negative - checks both good/bad results
- boundary value analysis
- decision tables
- equivalence partitioning - group related inputs/outputs
- state-based - based on object state diagrams
- compatibility testing
- user documentation testing
- domain testing
Boundary testing

- **boundary value analysis**: Testing conditions on bounds between classes of inputs.

- Why is it useful to test near boundaries?
  
  - likely source of programmer errors (< vs. <=, etc.)
  - language has many ways to implement boundary checking
  - requirement specs may be fuzzy about behavior on boundaries
  - often uncovers internal hidden limits in code
    - example: array list must resize its internal array when it fills capacity
Boundary example

• Imagine we are testing a `Date` class with a `daysInMonth(month, year)` method.
  – What are some conditions and boundary tests for this method?

• Possible answers:
  – check for leap years (every 4th yr, no 100s, yes 400s)
  – try years such as: even 100s, 101s, 4s, 5s
  – try months such as: June, July, Feb, invalid values
## Decision tables

</table>
Equivalence testing

• **equivalence partitioning:**
  – A black-box test technique to reduce # of required test cases.
  – What is it?

  – steps in equivalence testing:
    • identify classes of inputs with same behavior
    • test on at least one member of each equivalence class
    • assume behavior will be same for all members of class

  – criteria for selecting equivalence classes:
    • *coverage*: every input is in one class
    • *disjointedness*: no input in more than one class
    • *representation*: if error with 1 member of class, will occur with all
Some kinds of white box testing don't involve unit tests:

- "static testing"
  - code walkthroughs, inspections, code reviews
  - static analysis tools
    - Lint (and variants)  JiveLint, JLint, PMD, CheckR, JSLint, php -1
    - CheckStyle  http://checkstyle.sourceforge.net/
    - FindBugs  http://findbugs.sourceforge.net/
  - code complexity analysis tools
    - PMD, CheckStyle, etc.
Static analysis example

Method ignores exceptional return value

This method returns a value that is not checked. The return value should be checked since it can indicate an unusual or unexpected function execution. For example, the `File.delete()` method returns false if the file could not be successfully deleted (rather than throwing an Exception). If you don't check the result, you won't notice if the method invocation signals unexpected behavior by returning an atypical return value.
Complexity analysis

```
package ttt.model;
import java.util.*;
import com.sun.org.apache.regexp.internal.RE;

/** Models a tic-tac-toe game board. */
public class TTTGame extends Observable {
    // constants

    /** The tic-tac-toe board's width and height */
    public static final int BOARD_SIZE = 3;

    /** Constants that occupy board squares. */
```

Path testing

- **path testing**: an attempt to use test input that will pass once over each path in the code

  - path testing is *white box*

- What would be path testing for `daysInMonth(month, year)`?
  
  some ideas:
  - error input: year < 1, month < 1, month > 12
  - one month from [1, 3, 5, 7, 10, 12]
  - one month from [4, 6, 9, 11]
  - month 2
  - in a leap year, not in a leap year
• **code coverage testing**: Examines what fraction of the code under test is reached by existing unit tests.
  
  – statement coverage - tries to reach every line (impractical)
  
  – path coverage - follow every distinct branch through code
  
  – condition coverage - every condition that leads to a branch
  
  – function coverage - treat every behavior / end goal separately
  
• Several nice tools exist for checking code coverage
  
  – EclEmma, Cobertura, Hansel, NoUnit, CoView ...
Code coverage example

```java
public Date(int year, int month, int day) {
    this.year = year;
    this.month = month;
    this.day = day;
}

if (month < 1 || month > 12 || day < 1) {
    throw new IllegalArgumentException("Invalid day");
}

/** Constructs a new object representing today's date. */
public Date() {
    this(1970, JANUARY, 1);
    int daysSinceEpoch = (int) ((System.currentTimeMillis() / 1000) / 86400L);
```
Path coverage example

1. If \((\text{mm} < 1 \text{ or } \text{mm} > 12)\)
   - A: True
     - Invalid Date

2. If \((\text{mm} == 2)\)
   - C: False
     - \(D\: False\)
     - E: True
       - Daysofmonth[2] = 29;
     - F: False
       - Daysofmonth[2] = 28

3. If \((\text{dd} < \text{DaysofMonth}[\text{mm}] \text{ or } \text{dd} > \text{DaysofMonth}[\text{mm}])\)
   - G: True
     - Invalid Date
   - H: False
     - Valid Date
White box testing is hard

• Developers can't easily spot flaws in their own code.

• Test cases that are too focused on code may not be thinking about how the class is actually going to be used.

• Code coverage tools can give a false sense of security.
  – Just because code is "covered" doesn't mean it is free of bugs.

• Code complexity can be misleading.
  – Complex code is not always bad code.
  – Complexity analysis tools can be overly picky or cumbersome.
Imagine that we have a Date class with working methods called isLeapYear(year) and daysInMonth(month, year).

- Question: What is the pseudo-code for the algorithm for an addDays(days) method that moves the current Date object forward in time by the given number of days. A negative value moves the Date backward in time.

- Question: Come up with a set of test values for your addDays method to test its correctness.
Testing exercise 2

- Consider tests to determine whether a Scrabble move is legal:
  - Are all tiles in a straight line?
  - Are the tiles contiguous or separated only by existing old tiles?
  - Are the tiles touching an existing old tile?

- On each of the words made:
  - What is the score of this word?
  - Is this word in the dictionary?

- Question: What is/are some suitable Scrabble test board configuration(s) and moves that check each of these conditions?
  - Make both passing and failing tests.
