## CSE 410

Computer Systems

Hal Perkins
Spring 2010
Lecture 2 - Information Representation

## Reading and References

- Reading
- Computer Organization and Design, Patterson and Hennessy
- Chapter 2, sec. 2.4, 2.9 (first page only for now)

## Review: A Computer is ...

## Processor \& Memory

- For now we focus on the processor \& memory
- Processor operation
- Fetch next instruction from memory
- Fetch instruction operands (data) from memory
- Perform operation (add, subtract, test, ...)
- Store result (if any) in memory
- Repeat
- Billions of times a second
- Memory holds all instructions and data
- What is memory made of?

## Bits

- All memories are composed of (billions of) bits
- A bit is:
- high or low voltage
- 0 or 1
- true or false
- yes or no
- on or off

It's all how you interpret it

- But to store anything complicated we use a bunch of bits to make up a number, character, instruction, ...

## Computer Memory

- All memories are organized by grouping sets of bits into individual memory cells
- Each cell has an address and its contents
- Standard organization now: 1 cell = 8 bits = 1 byte
- A single byte can hold
- A small integer (0-255 or -128-127)
- A single character ('a', ‘A’, ‘?’, ‘\#', ‘ ', ...)
- A boolean value (00000000, 00000001)

## Memory Organization

- Memory is a linear array of bytes; each byte has an address (or location) - not the same as its contents

- Groups of bytes can be treated as a single unit

## Some common storage units

- Terminology varies: this is how MIPS does it; the Intel x86 calls 16 bits a word \& 32 bits a double-word

## Alignment

- An object in memory is "aligned" when its address is a multiple of its size
- Byte: always aligned
- Halfword: address is multiple of 2
- Word: address is multiple of 4
- Double word: address is multiple of 8
- Alignment simplifies load/store hardware
- And is required by MIPS, but not x86

## Binary Arithmetic

- Just as we do with decimal numbers, we can treat a collection of bits as a multi-digit number in base 2
- Example: $1010_{2}=1 \times 2^{3}+0 \times 2^{2}+1 \times 2^{1}+0 \times 2^{0}$

- You try it: 11001 = $\qquad$ ?

## Binary, Hex, and Decimal

- It's unwieldy to work with long strings of binary digits, so we group them in chunks of 4 and treat each chunk as a digit in base 16
- Hex digits:

$$
\begin{aligned}
& -\quad 0=0000, \quad 1=0001, \quad 2=0010, \quad 3=0011 \\
& -4=0100,5=0101,6=0110,7=0111 \\
& -8=1000,9=1001, \ldots=1010, \ldots=1011 \\
& \__{\ldots}=1100, \ldots=1101, \ldots=1110, \ldots=1111
\end{aligned}
$$

- Usual notation for hex integer in C, Java, ...: 0x1c4

## Hex Numbers

- What is $0 \times 2 \mathrm{a} 5$ in decimal?
$-0 \times 2 a 5=2 \times 16^{2}+a \times 16^{1}+5 \times 16^{0}$

$$
=
$$

$\qquad$

- What about 0xbad?
- Be sure you realize that $0 \times 11 \neq 11_{10} \neq 11_{2}$

## More problems

- What is $605_{10}$ in hex?
- What is 0xbeef in binary?
- (Hint: there's a trick)

## Binary, Hex, and Decimal

| $B^{\text {Binary }} 2$ | $\mathrm{Hex}_{16}$ |  | $\begin{aligned} & \stackrel{\odot}{\circ} \\ & \stackrel{\circ}{-} \\ & \stackrel{1}{N} \\ & \stackrel{+}{-} \\ & \stackrel{\rightharpoonup}{1} \end{aligned}$ | $\begin{aligned} & \stackrel{\ominus}{-} \\ & \stackrel{+}{-} \\ & \text { II } \\ & \stackrel{\rightharpoonup}{-} \end{aligned}$ | $\stackrel{\ominus}{-}$ <br> $\stackrel{11}{\circ}$ <br> $\stackrel{+}{-}$ |

| 11111111 |  |  |  | F | F | 255 |

## Unsigned binary numbers

- Each bit represents a power of 2
- For unsigned numbers in a fixed width n-bit field:
$-2^{n}$ distinct values
- the minimum value is 0
- the maximum value is $2^{n-1}$, where n is the number of bits in the field
- Fixed field widths determine many limits
-5 bits $=32$ possible values $\left(2^{5}=32\right)$
-10 bits $=1024$ possible values $\left(2^{10}=1024\right)$

## Signed Numbers

- For unsigned numbers,
- each bit position represents a power of 2
- range of values is 0 to $2^{n}-1$
- How can we indicate negative values?
- two states: positive or negative
- a binary bit indicates one of two states: 0 or 1
$\Rightarrow$ use one bit for the sign bit

## Where is the sign bit?

- Could use an additional bit to indicate sign
- each value would require 33 bits
- would really foul up the hardware design
- Could use any bit in the 32-bit word
- any bit but the left-most (high order) would complicate the hardware tremendously
- $\therefore$ The high order bit (left-most) is the sign bit
- remaining bits indicate the value

## Format of 32-bit signed integer

sign bit
(1 bit)

- 0 for positive numbers, 1 for negative numbers
- aka most significant bit (msb), high order bit

## Example: 4-bit signed numbers

| Hex | Bin | Unsigned <br> Decimal | Signed <br> Decimal |
| :---: | :---: | :---: | :---: |
| F | 1111 | 15 | -1 |
| E | 1110 | 14 | -2 |
| D | 1101 | 13 | -3 |
| C | 1100 | 12 | -4 |
| B | 1011 | 11 | -5 |
| A | 1010 | 10 | -6 |
| 9 | 1001 | 9 | -7 |
| 8 | 1000 | 8 | -8 |
| 7 | 0111 | 7 | 7 |
| 6 | 0110 | 6 | 6 |
| 5 | 0101 | 5 | 5 |
| 4 | 0100 | 4 | 4 |
| 3 | 0011 | 3 | 3 |
| 2 | 0010 | 2 | 2 |
| 1 | 0001 | 1 | 1 |
| 0 | 0000 | 0 | 0 |

sign bit
(1 bit)

## Two's complement notation

- Note special arrangement of negative values
- One zero value, one extra negative value
- The representation is exactly what you get by doing a subtraction

| Decimal | Binary |
| :---: | :---: |
| 1 | 0001 |
| -7 | -0111 |
| --- | --- |
| -6 | 1010 |

## Why "two's" complement?

- In an n-bit binary word, negative $x$ is represented by the value of $2^{n}-x$. The radix (or base) is 2 .
- 4-bit example
$2^{4}=16$. What is the representation of $-6 ?$

| Decimal | Binary |
| ---: | ---: |
|  |  |
| 16 | 10000 |
| $-\quad 6$ | - |
| --- | ---710 |
| 10 | 1010 |

## Negating a number

- Given $x$, how do we represent negative $x$ ?

$$
\text { negative(x) }=2^{n-x}
$$

and $\mathrm{x}+$ complement $(\mathrm{x})=2^{\mathrm{n}}-1$
so $\quad$ negative $(x)=2^{n}-x=$ complement( $\left.x\right)+1$

- The easy shortcut
- write down the value in binary
- complement all the bits
- add 1

## Example: the negation shortcut

$$
\begin{aligned}
\text { decimal } 6 & =0110=+6 \\
\text { complement } & =1001 \\
\text { add } 1 & =1010=-6 \\
\text { decimal }-6 & =1010=-6 \\
\text { complement } & =0101 \\
\text { add } 1 & =0110=+6
\end{aligned}
$$

## Why 2's complement? (Again)

- The key advantage is that we can add two numbers together without paying any attention to the sign and we get the properly signed result

## What About Non-Numeric Data?

- Everything is bits
- So assign (arbitrarily) specific bit patterns (numbers) to represent different characters
- Two most common codes
- ASCII - original 7-bit code, early 1960's
- How many possible characters?
- Unicode - 16- to 32-bit code to represent enough different characters to encode all currently used alphabets; started in the late 1980s

## ASCII

| 32 | space |
| :---: | :---: |
| 33 | $!$ |
| 34 | $"$ |
| 35 | $\#$ |
| 36 | $\$$ |

| 109 | m | 125 | \} |
| 110 | n | 126 | $\sim$ |
| 111 | 0 | 127 | del |

## But wait, there's more!

- We still haven't looked at
- Floating-point numbers (scientific notation)
- Strings/arrays
- Records/structs/objects
- Colors and images
- Sounds
- We'll see some of this, but it's all encoded as numbers (i.e., collections of bits)
- But next we need to look at how the computer processes these things - instructions
