# CSE 410 Computer Systems

Hal Perkins
Spring 2010
Lecture 20 – Virtual Memory

# Reading and References

- Reading: Computer Organization and Design, Patterson and Hennessy
  - Section 5.4 Virtual Memory
  - Section 5.5 A Common Framework for Memory Hierarchies

### Virtual Memory (and Indirection)

- Virtual Memory
  - We'll talk about the motivations for virtual memory
  - We'll talk about how it is implemented
  - Lastly, we'll talk about how to make virtual memory fast:
     Translation Lookaside Buffers (TLBs).

#### A Real Problem

- What if you wanted to run a program that needs more memory than you have?
  - You could store the whole program on disk, and use memory as a cache for the data on disk. This is one feature of virtual memory.
  - Before virtual memory, programmers had to manually manage loading "overlays" (chunks of instructions & data) off disk before they were used. This is an incredibly tedious, not to mention errorprone, process.

#### More Real Problems

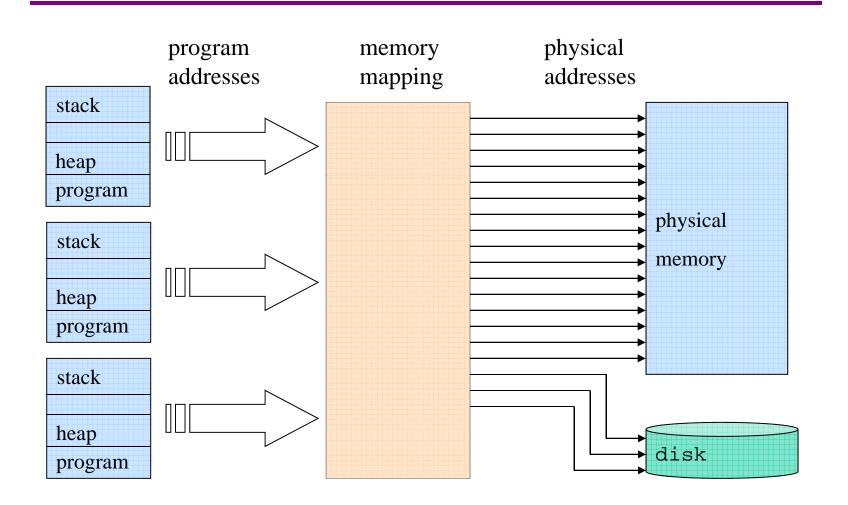

Running multiple programs at the same time brings up more problems.

- 1. Even if each program fits in memory, running 10 programs might not.
  - This is really the same problem as on the previous slide.
- 1. Multiple programs may want to store something at the same address.
  - i.e., what if both Program A and B want to use address 0x10000000 as the base of their stack?
  - It is impractical (if not impossible) to compile every pair of programs that could get executed together to use distinct sets of addresses.
- 2. How do we protect one program's data from being read or written by another program?

#### The Big Idea

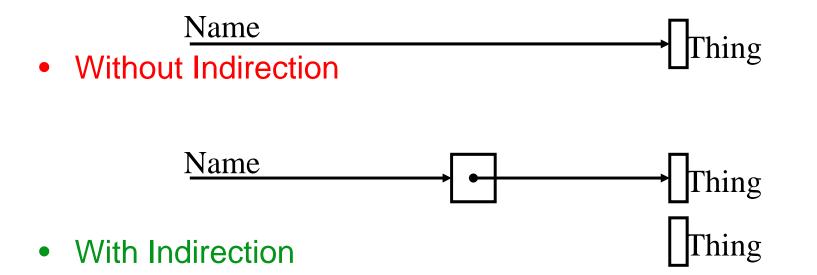

- Separate program notion of memory addresses from actual physical memory locations
  - Program memory = virtual addresses
  - Physical memory = real addresses
  - Use hardware to map between the two

# **Memory Mapping**

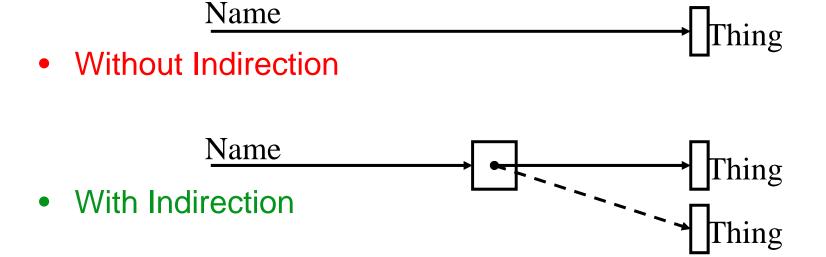

#### Indirection

 "Any problem in CS can be solved by adding a level of indirection"

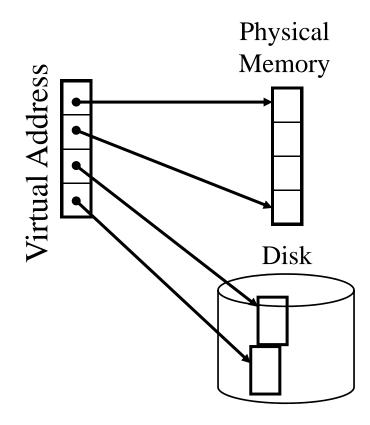

#### Indirection

 Indirection: Indirection is the ability to reference something using a name, reference, or container instead the value itself. A flexible mapping between a name and a thing allows changing the thing without notifying holders of the name.

### Virtual Memory

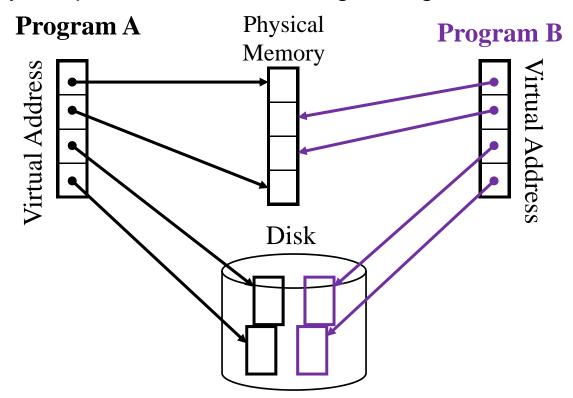

- We translate "virtual addresses" used by the program to "physical addresses" that represent places in the machine's "physical" memory.
  - The word "translate" denotes a level of indirection

A virtual address can be mapped to either physical memory or disk.

### Virtual Memory

- Because different processes will have different mappings from virtual to physical addresses, two programs can freely use the same virtual address.
- By allocating distinct regions of physical memory to A and B, they are prevented from reading/writing each others data.

### Caching revisited

- Once the translation infrastructure is in place, the problem boils down to caching.
  - We want the size of disk, but the performance of memory.
- The design of virtual memory systems is really motivated by the high cost of accessing disk.
  - While memory latency is ~100 times that of cache, disk latency is ~100,000 times that of memory.
- Hence, we try to minimize the miss rate:
  - VM "pages" are much larger than cache blocks. Why?
  - A fully associative policy is used.
    - With approximate LRU
- Should a write-through or write-back policy be used?

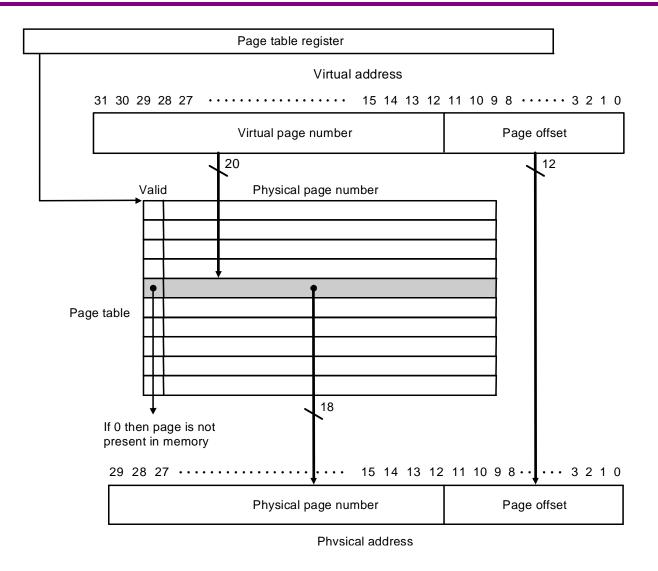

# Finding the right page

• If it is fully associative, how to we find the right page without scanning all of memory?

### Finding the right page

- If it is fully associative, how do we find the right page without scanning all of memory?
  - Use an index, just like you would for a book.
- Our index happens to be called the page table:
  - Each process has a separate page table
    - A "page table register" points to the current process's page table
  - The page table is indexed with the virtual page number (VPN)
    - The VPN is all of the bits that aren't part of the page offset.
  - Each entry contains a valid bit, and a physical page number (PPN)
    - The PPN is concatenated with the page offset to get the physical address
  - No tag is needed because the index is the full VPN.

# Page Table picture

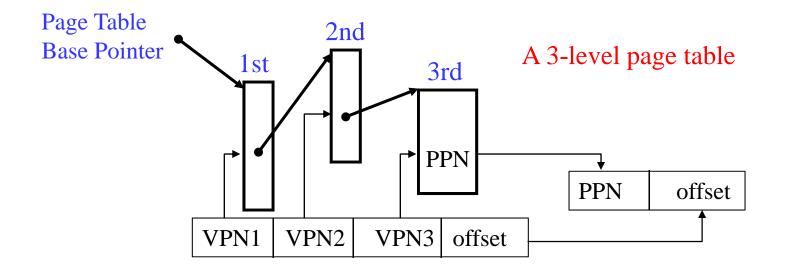

# How big is the page table?

- From the previous slide:
  - Virtual page number is 20 bits.
  - Physical page number is 18 bits + valid bit -> round up to 32 bits.

# Dealing with large page tables

- Multi-level page tables
  - "Any problem in CS can be solved by adding a level of indirection"
     or two...

- Since most processes don't use the whole address space, you don't allocate the tables that aren't needed
  - Also, the 2nd and 3rd level page tables can be "paged" to disk.

#### Waitaminute!

We've just replaced every memory access MEM[addr] with:

```
MEM[MEM[MEM[PTBR + VPN1<<2] + VPN2<<2] + VPN3<<2] + offset]
```

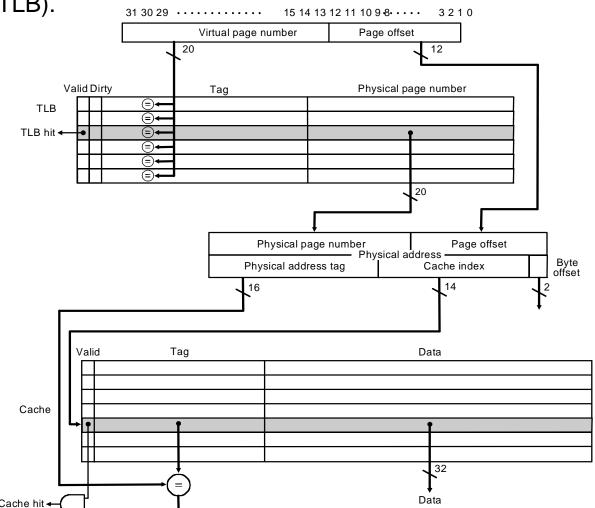

- *i.e.*, 4 memory accesses
- And we haven't talked about the bad case yet (i.e., page faults)...

"Any problem in CS can be solved by adding a level of indirection"

- except too many levels of indirection...

How do we deal with too many levels of indirection?

# **Caching Translations**

#### What about a TLB miss?

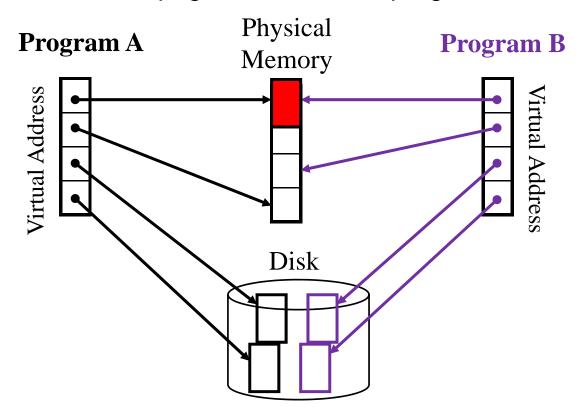

- If we miss in the TLB, we need to "walk the page table"
  - In MIPS, an exception is raised and software fills the TLB
  - In x86, a "hardware page table walker" fills the TLB
- What if the page is not in memory?
  - This situation is called a page fault.
  - The operating system will have to request the page from disk.
  - It will need to select a page to replace.
    - The O/S tries to approximate LRU (coming next)
  - The replaced page will need to be written back if dirty.

#### **Memory Protection**

- In order to prevent one process from reading/writing another process's memory, we must ensure that a process cannot change its virtual-to-physical translations.
- Typically, this is done by:
  - Having two processor modes: user & kernel.
    - Only the O/S runs in kernel mode
  - Only allowing kernel mode to write to the virtual memory state, e.g.,
    - The page table
    - The page table base pointer
    - The TLB

# **Sharing Memory**

- Paged virtual memory enables sharing at the granularity of a page, by allowing two page tables to point to the same physical addresses.
- For example, if you run two copies of a program, the O/S will share the code pages between the programs.

### Summary

- Virtual memory is great:
  - It means that we don't have to manage our own memory.
  - It allows different programs to use the same memory.
  - It provides protect between different processes.
  - It allows controlled sharing between processes (albeit somewhat inflexibly).
- The key technique is **indirection**:
  - Yet another classic CS trick you've seen in this class.
  - Many problems can be solved with indirection.
- Caching made a few appearances, too:
  - Virtual memory enables using physical memory as a cache for disk.
  - We used caching (in the form of the Translation Lookaside Buffer) to make Virtual Memory's indirection fast.
