Problem – how do we count inversions between sub problems in O(n) time?	
 Solution – Count inversions while merging 	
1 2 3 4 7 11 12 15 5 6 8 9 10 13 14 1	16
Standard merge algorithm – add to inversion count when an element is moved from the upper array to the solution

Packing Lemma

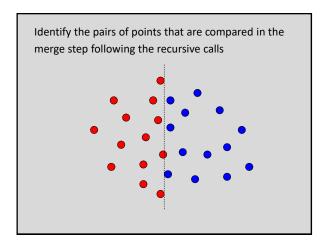

Suppose that the minimum distance between points is at least δ , what is the maximum number of points that can be packed in a ball of radius δ ?

Combining Solutions

- Suppose the minimum separation from the sub problems is $\boldsymbol{\delta}$
- In looking for cross set closest pairs, we only need to consider points with δ of the boundary
- How many cross border interactions do we need to test?

Details Preprocessing: sort points by y Merge step Select points in boundary zone For each point in the boundary Find highest point on the other side that is at most δ above Find lowest point on the other side that is at most δ below Compare with the points in this interval (there are at most 6)

Algorithm run time

After preprocessing:
 T(n) = cn + 2 T(n/2)
