CSE 451: Operating Systems Winter 2003

Lecture 6 Scheduling

Hank Levy levy@cs.washington.edu 412 Sieg Hall

Scheduling

- In discussion process management, we talked about context switching between threads/process on the ready queue
 - but, we glossed over the details of which process or thread is chosen next
 - making this decision is called scheduling
 - scheduling is policy
 - context switching is mechanism
- Today, we'll look at:
 - the goals of scheduling
 - starvation
 - well-known scheduling algorithms
 - standard UNIX scheduling

Multiprogramming and Scheduling

- Multiprogramming increases resource utilization and job throughput by overlapping I/O and CPU
 - today: look at scheduling policies
 - which process/thread to run, and for how long
 - schedulable entities are usually called jobs
 - processes, threads, people, disk arm movements, ...
- There are two time scales of scheduling the CPU:
 - long term: determining the multiprogramming level
 - how many jobs are loaded into primary memory
 - act of loading in a new job (or loading one out) is swapping
 - short-term: which job to run next to result in "good service"
 - happens frequently, want to minimize context-switch overhead
 - good service could mean many things

Scheduling

- The scheduler is the module that moves jobs from queue to queue
 - the scheduling algorithm determines which job(s) are chosen to run next, and which queues they should wait on
 - the scheduler is typically run when:
 - a job switches from running to waiting
 - when an interrupt occurs
 - especially a timer interrupt
 - when a job is created or terminated
- There are two major classes of scheduling systems
 - in preemptive systems, the scheduler can interrupt a job and force a context switch
 - in non-preemptive systems, the scheduler waits for the running job to explicitly (voluntarily) block

Scheduling Goals

- Scheduling algorithms can have many different goals (which sometimes conflict)
 - maximize CPU utilization
 - maximize job throughput (#jobs/s)
 - minimize job turnaround time (T_{finish} T_{start})
 - minimize job waiting time (Avg (T_{wait}): average time spent on wait queue)
 - minimize response time (Avg(T_{resp}): average time spent on ready queue)
- Goals may depend on type of system
 - batch system: strive to maximize job throughput and minimize turnaround time
 - interactive systems: minimize response time of interactive jobs (such as editors or web browsers)

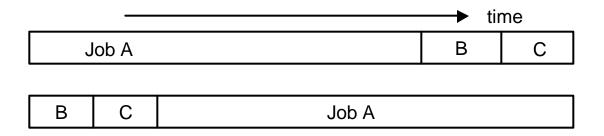

Scheduler Non-goals

- Schedulers typically try to prevent starvation
 - starvation occurs when a process is prevented from making progress, because another process has a resource it needs
- A poor scheduling policy can cause starvation
 - e.g., if a high-priority process always prevents a low-priority process from running on the CPU
- Synchronization can also cause starvation
 - we'll see this in a future class
 - roughly, if somebody else always gets a lock I need, I can't make progress

Algorithm #1: FCFS/FIFO

- First-come first-served (FCFS)
 - jobs are scheduled in the order that they arrive
 - "real-world" scheduling of people in lines
 - e.g. supermarket, bank tellers, MacDonalds, ...
 - typically non-preemptive
 - no context switching at supermarket!
 - jobs treated equally, no starvation
 - except possibly for infinitely long jobs
- Sounds perfect!
 - what's the problem?

FCFS picture

Problems:

- average response time and turnaround time can be large
 - e.g., small jobs waiting behind long ones
 - results in high turnaround time
- may lead to poor overlap of I/O and CPU

Algorithm #2: SJF

- Shortest job first (SJF)
 - choose the job with the smallest expected CPU burst
 - can prove that this has optimal min. average waiting time
- Can be preemptive or non-preemptive
 - preemptive is called shortest remaining time first (SRTF)
- Sounds perfect!
 - what's the problem here?

SJF Problem

- Problem: impossible to know size of future CPU burst
 - from your theory class, equivalent to the halting problem
 - can you make a reasonable guess?
 - yes, for instance looking at past as predictor of future
 - but, might lead to starvation in some cases!

Priority Scheduling

- Assign priorities to jobs
 - choose job with highest priority to run next
 - if tie, use another scheduling algorithm to break (e.g. FCFS)
 - to implement SJF, priority = expected length of CPU burst
- Abstractly modeled as multiple "priority queues"
 - put ready job on queue associated with its priority
- Sound perfect!
 - what's wrong with this?

Priority Scheduling: problem

- The problem: starvation
 - if there is an endless supply of high priority jobs, no lowpriority job will ever run
- Solution: "age" processes over time
 - increase priority as a function of wait time
 - decrease priority as a function of CPU time
 - many ugly heuristics have been explored in this space

Round Robin

- Round Robin scheduling (RR)
 - ready queue is treated as a circular FIFO queue
 - each job is given a time slice, called a quantum
 - job executes for duration of quantum, or until it blocks
 - time-division multiplexing (time-slicing)
 - great for timesharing
 - no starvation
 - can be preemptive or non-preemptive
- Sounds perfect!
 - what's wrong with this?

RR problems

• Problems:

- what do you set the quantum to be?
 - no setting is "correct"
 - if small, then context switch often, incurring high overhead
 - if large, then response time drops
- treats all jobs equally
 - if I run 100 copies of SETI@home, it degrades your service
 - how can I fix this?

Combining algorithms

- Scheduling algorithms can be combined in practice
 - have multiple queues
 - pick a different algorithm for each queue
 - and maybe, move processes between queues
- Example: multi-level feedback queues (MLFQ)
 - multiple queues representing different job types
 - batch, interactive, system, CPU-bound, etc.
 - queues have priorities
 - schedule jobs within a queue using RR
 - jobs move between queues based on execution history
 - "feedback": switch from CPU-bound to interactive behavior
- Pop-quiz:
 - is MLFQ starvation-free?

UNIX Scheduling

- Canonical scheduler uses a MLFQ
 - 3-4 classes spanning ~170 priority levels
 - timesharing: first 60 priorities
 - system: next 40 priorities
 - real-time: next 60 priorities
 - priority scheduling across queues, RR within
 - process with highest priority always run first
 - processes with same priority scheduled RR
 - processes dynamically change priority
 - increases over time if process blocks before end of quantum
 - decreases if process uses entire quantum
- Goals:
 - reward interactive behavior over CPU hogs
 - interactive jobs typically have short bursts of CPU
