CSE 451: Operating Systems Winter 2006

Module 6 Synchronization

Ed Lazowska lazowska@cs.washington.edu Allen Center 570

- For correctness, we have to control this cooperation
 - must assume threads interleave executions arbitrarily and at different rates
 - · scheduling is not under application writers' control
- We control cooperation using synchronization
 - enables us to restrict the interleaving of executions
- Note: this also applies to processes, not just threads

 (I'll almost never say "process" again!)

 It also applies across machines in a distributed system

Shared resources

- We'll focus on coordinating access to shared resources
 - basic problem:
 - two concurrent threads are accessing a shared variable
 - if the variable is read/modified/written by both threads, then access to the variable must be controlled
 - otherwise, unexpected results may occur
- Over the next several lectures, we'll look at:
 - mechanisms to control access to shared resources
 - low level mechanisms like locks
 - higher level mechanisms like mutexes, semaphores, monitors, and condition variables
 - patterns for coordinating access to shared resources
 - bounded buffer, producer-consumer, ...

The classic example

 Suppose we have to implement a function to withdraw money from a bank account:

int withdraw(account, amount) {
 balance = get_balance(account);
 balance -= amount;
 put_balance(account, balance);
 return amount;
}

- Now suppose that you and your S.O. share a bank account with a balance of \$100.00
 - what happens if you both go to separate ATM machines, and simultaneously withdraw \$10.00 from the account?

1/15/2006 © 2006 Gribble, Lazowska, Levy 5

- Represent the situation by creating a separate thread for each person to do the withdrawals
 - have both threads run on the same bank mainframe:

int withdraw(account, amount) {
 balance = get_balance(account);
 balance -= amount;
 put_balance(account, balance);
 return amount;

int withdraw(account, amount) {
 balance = get_balance(account);
 balance -= amount;
 put_balance(account, balance);
 return amount;

Interleaved schedules

 The problem is that the execution of the two threads can be interleaved, assuming preemptive scheduling:

Execution sequence as seen by CPU balance = get_balance(account);
balance -= amount;
balance = get_balance(account);
balance -= amount;
put_balance(account, balance);
put_balance(account, balance);

· What's the account balance after this sequence?

- who's happy, the bank or you? ;)

The crux of the matter

- The problem is that two concurrent threads (or processes) access a shared resource (account) without any synchronization
 - creates a race condition
 - · output is non-deterministic, depends on timing
- We need mechanisms for controlling access to shared resources in the face of concurrency
 - so we can reason about the operation of programs
 - essentially, re-introducing determinism
- Synchronization is necessary for any shared data structure
 - buffers, queues, lists, hash tables, ...

What resources are shared?

- · Local variables are not shared
 - refer to data on the stack, each thread has its own stack
 - never pass/share/store a pointer to a local variable on another thread's stack!
- · Global variables are shared
 - stored in the static data segment, accessible by any thread
- · Dynamic objects are shared
 - stored in the heap, shared if you can name it
 - in C, can conjure up the pointer
 - e.g., void *x = (void *) 0xDEADBEEF
 - · in Java, strong typing prevents this

must pass references explicitly

Mutual exclusion

- We want to use mutual exclusion to synchronize access to shared resources
- Code that uses mutual exclusion to synchronize its execution is called a critical section
 - only one thread at a time can execute in the critical section
 - all other threads are forced to wait on entry
 - when a thread leaves a critical section, another can enter

12

Critical section requirements

- · Critical sections have the following requirements
 - mutual exclusion
 - at most one thread is in the critical section
 - progress
 - if thread T is outside the critical section, then T cannot prevent thread S from entering the critical section
 - bounded waiting (no starvation)
 - if thread T is waiting on the critical section, then T will eventually enter the critical section
 - assumes threads eventually leave critical sections
 - performance
 - the overhead of entering and exiting the critical section is small with respect to the work being done within it

Mechanisms for building critical sections

- Locks
 - very primitive, minimal semantics; used to build others
- Semaphores
 - basic, easy to get the hang of, hard to program with
- Monitors
- high level, requires language support, implicit operations
- easy to program with; Java "synchronized()" as an example
- Messages
 - simple model of communication and synchronization based on (atomic) transfer of data across a channel
 - direct application to distributed systems

- spinlock

1/15/2006

Problems with spinlocks

- Spinlocks work, but are horribly wasteful!
 - if a thread is spinning on a lock, the thread holding the lock cannot make progress
 - And neither can anyone else!
- Only want spinlocks as primitives to build higher-level synchronization constructs
 - "Do not try this at home!"

1/15/2006

Another approach: Disabling interrupts

```
struct lock {
}

void acquire(lock) {
   cli();    // disable interrupts
}

void release(lock) {
   sti();    // reenable interrupts
}
```

1/15/2006

Problems with disabling interrupts

- Only available to the kernel
 - Can't allow user-level to disable interrupts!
- · Insufficient on a multiprocessor
 - Each processor has its own interrupt mechanism
- "Long" periods with interrupts disabled can wreak havoc with devices
- Just as with spinlocks, you only want to use disabling of interrupts to build higher-level synchronization constructs

21

Summary

- Synchronization can be provided by locks, semaphores, monitors, messages ...
- · Locks are the lowest-level mechanism
 - very primitive in terms of semantics error-prone
 - implemented by spin-waiting (crude) or by disabling interrupts (also crude, and can only be done in the kernel)
- In our next exciting episode ...
 - semaphores are a slightly higher level abstraction
 - less crude implementation too
 - monitors are significantly higher level
 - utilize programming language support to reduce errors
