Geometric transformations

Geometric transformations will map points in one space to points in another: \((x', y', z') = f(x, y, z)\).

These transformations can be very simple, such as scaling each coordinate, or complex, such as non-linear twists and bends.

We’ll focus on transformations that can be represented easily with matrix operations.

We’ll start in 2D.

Vector representation

We can represent a point, \(p = (x, y)\), in the plane or \(p = (x, y, z)\) in 3D space:

- as column vectors
  \[
  \begin{bmatrix}
  x \\
  y \\
  \end{bmatrix}
  \]

- as row vectors
  \[
  \begin{bmatrix}
  x & y \\
  x & y \\
  \end{bmatrix}
  \]
**Canonical axes**

Right-handed coord systems

**Vector length and dot products**

\[
V = \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} \\
\|V\| = \sqrt{v_x^2 + v_y^2 + v_z^2}
\]

\[
u \cdot v = u_x v_x + u_y v_y + u_z v_z = \begin{bmatrix} u_x \\ u_y \\ u_z \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix}
\]

\[
u \cdot u = \|u\| \|v\| \cos \theta = u^T v
\]

\[
u \cdot v = 0 \quad \text{if} \quad \|u\| \|v\| > 0 \Rightarrow u \perp v \quad \text{orthogonal}
\]

\[
u \cdot u = \|u\|^2
\]

\[
v = \|V\| \hat{v} \\
\hat{v} = \frac{v}{\|v\|}
\]

\[
\theta = \cos^{-1} \left( \frac{\nu \cdot u}{\|u\| \|v\|} \right)
\]

**Vector cross products**

\[
u \times v = \begin{vmatrix}
\mathbf{i} & \mathbf{j} & \mathbf{k} \\
u_x & u_y & u_z \\
v_x & v_y & v_z
\end{vmatrix}
\]

\[
\|u \times v\| = \text{Area}(\overrightarrow{uv}) = \|u\| \|v\| \sin \theta
\]

\[
(u \times v) \cdot u = 0
\]

\[
(u \times v) \cdot v = 0
\]

\[
u \times v = -v \times u
\]

\[
\frac{1}{2} \|u \times v\| = \text{Area}(A_{uv})
\]

**Representation, cont.**

We can represent a 2-D transformation \( M \) by a matrix

\[
\begin{bmatrix} a & b \\ c & d \end{bmatrix}
\]

\[
(A \cdot B)^T = B^T A^T
\]

\[
(A \cdot B)^T (A \cdot B) = I
\]

\[
(A \cdot B)^T A = B^T
\]

\[
(A \cdot B)^T B = A^T
\]

If \( \mathbf{p} \) is a column vector, \( M \) goes on the left:

\[
\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} ax + by \\ cx + dy \end{bmatrix}
\]

If \( \mathbf{p} \) is a row vector, \( M^T \) goes on the right:

\[
\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a & c \\ b & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} ax + by \\ cx + dy \end{bmatrix}
\]

We will use column vectors.
Two-dimensional transformations

Here's all you get with a $2 \times 2$ transformation matrix $M$:

$$
\begin{bmatrix}
x' \\
y'
\end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\
y
\end{bmatrix}
$$

So:

$$x' = ax + by$$
$$y' = cx + dy$$

We will develop some intimacy with the elements $a, b, c, d, ...$

Identity

Suppose we choose $a=d=1, b=c=0$.

- Gives the identity matrix:

$$
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\begin{bmatrix} x \\
y
\end{bmatrix} =
\begin{bmatrix} x \\
y
\end{bmatrix}
$$

- Doesn't move the points at all

Scaling

Suppose we set $b=c=0$, but let $a$ and $d$ take on any positive value.

- Gives a scaling matrix:

$$
\begin{bmatrix}
a & 0 \\
0 & d
\end{bmatrix}
$$

- Provides differential (non-uniform) scaling in $x$ and $y$:

$$x' = ax$$
$$y' = dy$$

Examples:

$$
\begin{bmatrix}
2 & 0 \\
0 & 2
\end{bmatrix}
\begin{bmatrix} x \\
y
\end{bmatrix} =
\begin{bmatrix} 2x \\
2y
\end{bmatrix}
$$

Reflection

Suppose we keep $b=c=0$, but let either $a$ or $d$ go negative.

Examples:

$$
\begin{bmatrix}
-1 & 0 \\
0 & -1
\end{bmatrix}
\begin{bmatrix} x \\
y
\end{bmatrix} =
\begin{bmatrix} -x \\
y
\end{bmatrix}
$$

Not a reflection rotation by $180^\circ$.
Shear

Now let's leave $a=d=1$ and experiment with $b$...

The matrix

$$\begin{bmatrix} 1 & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} x+b \\ y \end{bmatrix}$$

gives:

$$x' = x + by$$
$$y' = y$$

Effect on unit square

Let's see how a general $2 \times 2$ transformation $M$ affects the unit square:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} p & q & r & s \\ 0 & 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & a+b & b \\ 0 & c+d & d \end{bmatrix}$$

Effect on unit square, cont.

Observe:

- Origin invariant under $M$
- $M$ can be determined just by knowing how the corners $(1,0)$ and $(0,1)$ are mapped
- $a$ and $d$ give x-and y-scaling
- $b$ and $c$ give x-and y-shearing

Rotation

From our observations of the effect on the unit square, it should be easy to write down a matrix for "rotation about the origin":

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix} \rightarrow \begin{bmatrix} \cos \theta \\ \sin \theta \end{bmatrix}$$

$$\begin{bmatrix} 0 \\ 1 \end{bmatrix} \rightarrow \begin{bmatrix} -\sin \theta \\ \cos \theta \end{bmatrix}$$

Thus:

$$M = R(\theta) = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$$
Degrees of freedom

For any transformation, we can count its degrees of freedom—the number of independent (though not necessarily unique) parameters needed to specify the transformation.

One way to count them is to add up all the apparently free variables and subtract the number of equations that constrain them.

How many degrees of freedom does an arbitrary 2x2 transformation have?

How many degrees of freedom does a 2D rotation have?

\[
\begin{bmatrix}
1 & \nu \\
\nu & 1
\end{bmatrix}
\begin{aligned}
u \cdot \nu &= 0 \\
u \cdot u &= 1
\end{aligned}
\]

\[4 - 3 = 1\]

Homogeneous coordinates

We can lift the problem up into 3-space, adding a third component to every point:

\[
\begin{bmatrix}
x' \\
y' \\
w'
\end{bmatrix} = T(\mathbf{x})
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
x \\
y \\
w
\end{bmatrix}
\]

Adding the third "w" component puts us in homogenous coordinates.

Then, transform with a 3 x 3 matrix:

\[
\begin{bmatrix}
x'' \\
y'' \\
w''
\end{bmatrix} = T(\mathbf{x})
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
x' \\
y' \\
w'
\end{bmatrix}
\]

...gives translation!

Limitations of the 2 x 2 matrix

A 2 x 2 linear transformation matrix allows:

- Scaling
- Rotation
- Reflection
- Shearing

Q: What important operation does that leave out?

Translation

Affine transformations

The addition of translation to linear transformations gives us affine transformations.

In matrix form, 2D affine transformations always look like this:

\[
M = \begin{bmatrix}
a & b & \frac{c}{w} \\
b & d & \frac{e}{w} \\
0 & 0 & 1
\end{bmatrix}
\]

2D affine transformations always have a bottom row of [0 0 1].

An "affine point" is a "linear point" with an added w-coordinate which is always 1:

\[
P_{\text{aff}} = \begin{bmatrix}
x \\
y \\
1
\end{bmatrix}
\]

Applying an affine transformation gives another affine point:

\[
M_{p_{\text{aff}}} = \begin{bmatrix}
a & b & \frac{c}{w} \\
b & d & \frac{e}{w} \\
0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
x \\
y \\
1
\end{bmatrix}
\]
Rotation about arbitrary points

Until now, we have only considered rotation about the origin.

With homogeneous coordinates, you can specify a rotation, \( \theta \) about any point \( \mathbf{q} = [q_x, q_y, 1]^T \) with a matrix:

\[
M = T(\mathbf{q}) 
\quad R(\theta) 
\quad T(\mathbf{q})
\]

1. Translate \( \mathbf{q} \) to origin
2. Rotate
3. Translate back

Note: Transformation order is important!

Points and vectors

Vectors have an additional coordinate of \( w=0 \). Thus, a change of origin has no effect on vectors.

Q: What happens if we multiply a vector by an affine matrix?

These representations reflect some of the rules of affine operations on points and vectors:

- vector + vector \( \rightarrow \) vector
- scalar + vector \( \rightarrow \) vector
- point + point \( \rightarrow \) point
- point + vector \( \rightarrow \) point
- point + point \( \rightarrow \) chaos

One useful combination of affine operations is:

\[
\mathbf{p}(t) = \mathbf{p}_0 + t \mathbf{u}
\]

Q: What does this describe?

Translation in 3D

\[
\begin{bmatrix}
    x' \\
    y' \\
    z'
\end{bmatrix} =
\begin{bmatrix}
    1 & 0 & 0 & t_x \\
    0 & 1 & 0 & t_y \\
    0 & 0 & 1 & t_z \\
    0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
    x \\
    y \\
    z \\
    1
\end{bmatrix}
\]

Basic 3-D transformations: scaling

Some of the 3-D affine transformations are just like the 2-D ones.

In this case, the bottom row is always \([0 \ 0 \ 0 \ 1]\).

For example, scaling:

\[
\begin{bmatrix}
    x' \\
    y' \\
    z'
\end{bmatrix} =
\begin{bmatrix}
    s_x & 0 & 0 & 0 \\
    0 & s_y & 0 & 0 \\
    0 & 0 & s_z & 0 \\
    0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
    x \\
    y \\
    z \\
    1
\end{bmatrix}
\]
Rotation in 3D

Rotation now has more possibilities in 3D:

\[ R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha & 0 \\ 0 & \sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

\[ R_y(\beta) = \begin{bmatrix} \cos \beta & 0 & \sin \beta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \beta & 0 & \cos \beta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

\[ R_z(\gamma) = \begin{bmatrix} \cos \gamma & -\sin \gamma & 0 & 0 \\ \sin \gamma & \cos \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

Use right hand rule

Rotation in 3D (cont'd)

How many degrees of freedom are there in an arbitrary rotation?

\[ R^T R = \begin{bmatrix} u & v \\ v & w \end{bmatrix} \begin{bmatrix} u & v \\ v & w \end{bmatrix} = \begin{bmatrix} u^2 + v^2 & u v + v w \\ u v + v w & v^2 + w^2 \end{bmatrix} \]

\[ \begin{bmatrix} u \cdot u = 1 \\ u \cdot v = 0 \\ v \cdot v = 1 \\ w \cdot w = 1 \end{bmatrix} \]

\[ \begin{bmatrix} u + v = 2 \\ 2 = 3 \end{bmatrix} \]

Plane

\[ p(s,t) = p_0 + su \times \hat{n} \]

\[ \hat{n} \cdot x = d \]

How else might you specify a 3D rotation?

Properties of affine transformations

Here are some useful properties of affine transformations:

- Lines map to lines
- Parallel lines remain parallel
- Midpoints map to midpoints (in fact, ratios are always preserved)

We call this a shear with respect to the x-z plane.
Affine transformations in OpenGL

OpenGL maintains a "modelview" matrix that holds the current transformation $M$.

The modelview matrix is applied to points (usually vertices of polygons) before drawing.

It is modified by commands including:

- `glLoadIdentity()`  \quad $M \leftarrow I$
  \quad - set $M$ to identity

- `glTranslatef($t_x$, $t_y$, $t_z$)`  \quad $M \leftarrow MT$
  \quad - translate by $(t_x, t_y, t_z)$

- `glRotatef($\theta$, $x$, $y$, $z$)`  \quad $M \leftarrow MR$
  \quad - rotate by angle $\theta$ about axis $(x, y, z)$

- `glScalef($s_x$, $s_y$, $s_z$)`  \quad $M \leftarrow MS$
  \quad - scale by $(s_x, s_y, s_z)$

Note that OpenGL adds transformations by postmultiplication of the modelview matrix.

Summary

What to take away from this lecture:

- All the names in boldface.
- How points and transformations are represented.
- How to compute lengths, dot products, and cross products of vectors, and what their geometrical meanings are.
- What all the elements of a $2 \times 2$ transformation matrix do and how these generalize to $3 \times 3$ transformations.
- What homogeneous coordinates are and how they work for affine transformations.
- How to concatenate transformations.
- The mathematical properties of affine transformations.
