Hidden Markov Models &
Particle Filtering

Hanna Hajishirzi

Many slides adapted from Dan Weld, Pieter Abbeel, Dan Klein,
Stuart Russell, Andrew Moore & Luke Zettlemoyer
Outline

- Probabilistic sequence models (and inference)
  - Probability and Uncertainty – Preview
  - Markov Chains
  - Hidden Markov Models
  - Exact Inference
  - Particle Filters
  - Applications
Example

- A robot move in a discrete grid
  - May fail to move in the desired direction with some probability
- Observation from noisy sensor at each time
  - Is a function of robot position
- Goal: Find the robot position (probability that a robot is at a specific position)
- Cannot always compute this probability exactly
  - Approximation methods
    Here: Approximate a distribution by sampling
Hidden Markov Model

- **State Space Model**
  - **Hidden states**: Modeled as a Markov Process
  - \( P(x_0), P(x_k | x_{k-1}) \)
  - **Observations**: \( e_k \)
  - \( P(e_k | x_k) \)

Position of the robot

Observed position from the sensor
Filtering is the inference process of finding a distribution over $X_T$ given $e_1$ through $e_T$: $P(X_T | e_1:t)$

We first compute $P(X_1 | e_1)$:

$$P(x_1|e_1) \propto P(x_1) \cdot P(e_1|x_1)$$

For each $t$ from 2 to $T$, we have $P(X_{t-1} | e_{1:t-1})$

Elapse time: compute $P(X_t | e_{1:t-1})$

$$P(x_t|e_{1:t-1}) = \sum_{x_{t-1}} P(x_{t-1}|e_{1:t-1}) \cdot P(x_t|x_{t-1})$$

Observe: compute $P(X_t | e_{1:t-1}, e_t) = P(X_t | e_1:t)$

$$P(x_t|e_{1:t}) \propto P(x_t|e_{1:t-1}) \cdot P(e_t|x_t)$$
Approximate Inference:

- Sometimes $|X|$ is too big for exact inference
  - $|X|$ may be too big to even store $B(X)$
  - E.g. when $X$ is continuous
  - $|X|^2$ may be too big to do updates

- Solution: approximate inference by sampling
- How robot localization works in practice
What is Sampling?

- Goal: Approximate the original distribution:

- Approximate with Gaussian distribution

- Draw samples from a distribution close enough to the original distribution

- Here: A general framework for a sampling method
Approximate Solution: Perfect Sampling

Robot path till time $n$

Assume we can sample from the original distribution $p(x_{0:n} \mid y_{0:n})$.

\[
P(x_{0:n} \mid y_{0:n}) = \frac{1}{N} \quad \text{Number of samples that match with query}
\]

Converges to the exact value for large $N$.
Approximate Inference: Particle Filtering

- **Solution: approximate inference**
  - Track samples of X, not all values
  - Samples are called *particles*
  - Time per step is linear in the number of samples
  - But: number needed may be large
  - In memory: list of particles, not states

- **How robot localization works in practice**
Our representation of P(X) is now a list of N particles (samples)
  - Generally, \( N \ll |X| \)
  - Storing map from X to counts would defeat the point

P(x) approximated by number of particles with value x
  - So, many x will have \( P(x) = 0! \)
  - More particles, more accuracy

For now, all particles have a weight of 1
Particle Filtering: Elapse Time

- Each particle is moved by sampling its next position from the transition model

\[ x' = \text{sample}(P(X'|x)) \]

- This is like prior sampling – samples’ frequencies reflect the transition probs
- Here, most samples move clockwise, but some move in another direction or stay in place

- This captures the passage of time
  - If we have enough samples, close to the exact values before and after (consistent)
Particle Filtering: Observe

- How handle noisy observations?
- Suppose sensor gives red reading?
Particle Filtering: Observe

Slightly trickier:

- We don’t sample the observation, we fix it
- Instead: **downweight samples** based on the evidence (form of likelihood weighting)

\[
w(x) = P(e|x)
\]

\[
B(X) \propto P(e|X)B'(X)
\]

- Note: as before, probabilities **don’t sum to one**, since most have been downweighted (in fact they sum to an approximation of \(P(e)\))
Particle Filtering: Resample

- Rather than tracking weighted samples, we resample.

- N times, we choose from our weighted sample distribution (i.e. draw with replacement).

- This is equivalent to renormalizing the distribution.

- Now the update is complete for this time step, continue with the next one.

Old Particles:
(3,3) w=0.1
(2,1) w=0.9
(2,1) w=0.9
(3,1) w=0.4
(3,2) w=0.3
(2,2) w=0.4
(1,1) w=0.4
(3,1) w=0.4
(2,1) w=0.9
(3,2) w=0.3

New Particles:
(2,1) w=1
(2,1) w=1
(2,1) w=1
(3,2) w=1
(2,2) w=1
(2,1) w=1
(1,1) w=1
(3,1) w=1
(2,1) w=1
(1,1) w=1
Particle Filter (Recap)

- **Particles:** track samples of states rather than an explicit distribution
Particle Filtering Summary

- Represent current belief $P(X \mid \text{evidence to date})$ as set of $n$ samples (actual assignments $X=x$)

- For each new observation $e$:
  1. Sample transition, once for each current particle $x$
     \[ x' = \text{sample}(P(X' \mid x)) \]
  2. For each new sample $x'$, compute importance weights for the new evidence $e$:
     \[ w(x') = P(e \mid x') \]
  3. Finally, normalize by resampling the importance weights to create $N$ new particles
HMM Examples & Applications
P4: Ghostbusters

- **Plot**: Pacman's grandfather, Grandpac, learned to hunt ghosts for sport.

- He was blinded by his power, but could hear the ghosts’ banging and clanging.

- **Transition Model**: All ghosts move randomly, but are sometimes biased

- **Emission Model**: Pacman knows a “noisy” distance to each ghost

Noisy distance prob

True distance = 8

Which Algorithm?

Exact filter, uniform initial beliefs
Which Algorithm?

Particle filter, uniform initial beliefs, 25 particles
Which Algorithm?

Particle filter, uniform initial beliefs, 300 particles
Robot Localization

In robot localization:
- We know the map, but not the robot’s position
- Observations may be vectors of range finder readings
- State space and readings are typically continuous (works basically like a very fine grid) and so we cannot store $B(X)$
- Particle filtering is a main technique
Robot Localization

QuickTime™ and a GIF decompressor are needed to see this picture.
SLAM

- **SLAM = Simultaneous Localization And Mapping**
  - We do not know the map or our location
  - Our belief state is over maps and positions!
  - Main techniques: Kalman filtering (Gaussian HMMs) and particle methods

DP-SLAM, Ron Parr
Best Explanation Queries

- Query: most likely seq:

\[
\arg \max_{x_{1:t}} P(x_{1:t}|e_{1:t})
\]
State Path Trellis

- State trellis: graph of states and transitions over time
- Each arc represents some transition $x_{t-1} \rightarrow x_t$
- Each arc has weight $P(x_t|x_{t-1})P(e_t|x_t)$
- Each path is a sequence of states
- The product of weights on a path is the seq’s probability
- Can think of the Forward (and now Viterbi) algorithms as computing sums of all paths (best paths) in this graph
**Forward/Viterbi Algorithm**

![Diagram of states and transitions](image.png)

$X_1 \quad X_2 \quad \cdots \quad X_N$

**Forward Algorithm (Sum)**

$$f_t[x_t] = P(x_t, e_{1:t})$$

$$= P(e_t|x_t) \sum_{x_{t-1}} P(x_t|x_{t-1}) f_{t-1}[x_{t-1}]$$

**Viterbi Algorithm (Max)**

$$m_t[x_t] = \max_{x_{1:t-1}} P(x_{1:t-1}, x_t, e_{1:t})$$

$$= P(e_t|x_t) \max_{x_{t-1}} P(x_t|x_{t-1}) m_{t-1}[x_{t-1}]$$
