CSE 473: Artificial Intelligence

Spring 2014

A* Search

Hanna Hajishirzi

Based on slides from Luke Zettelemoyer, Dan Klein

Multiple slides from Stuart Russell or Andrew Moore

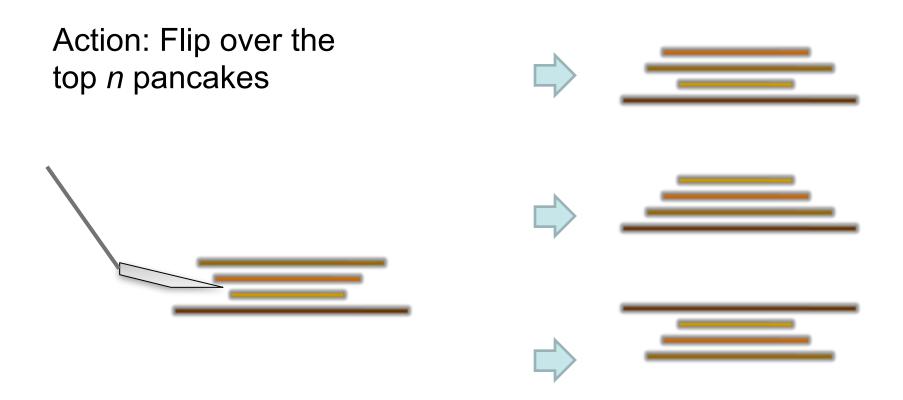

Announcements

- Programming assignment 1 is on the webpage
 - Start early
 - Due a week from Friday
 - Go to office hours and ask questions

Recap

- Rational Agents
- Problem state spaces and search problems
- Uninformed search algorithms
 - DFS
 - BFS
 - UCS
- Heuristics
 - Best First Greedy

Example: Pancake Problem

Cost: Number of pancakes flipped

Example: Pancake Problem

BOUNDS FOR SORTING BY PREFIX REVERSAL

William H. GATES

Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU**

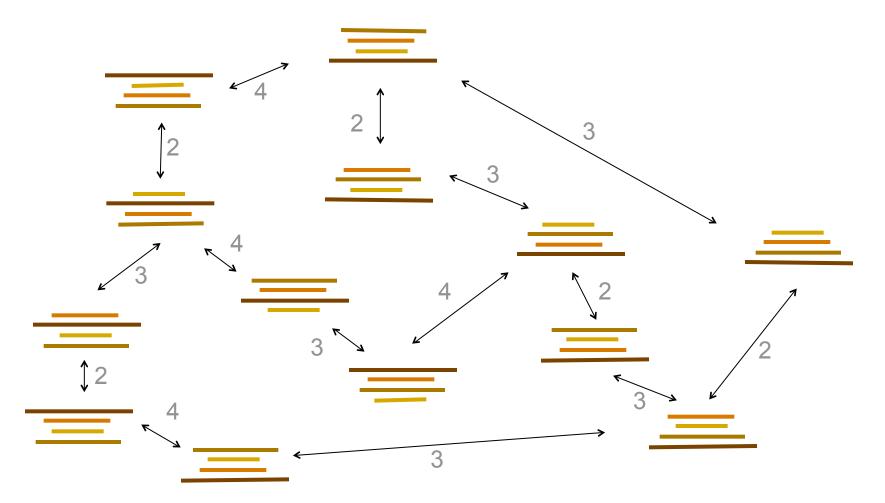

Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

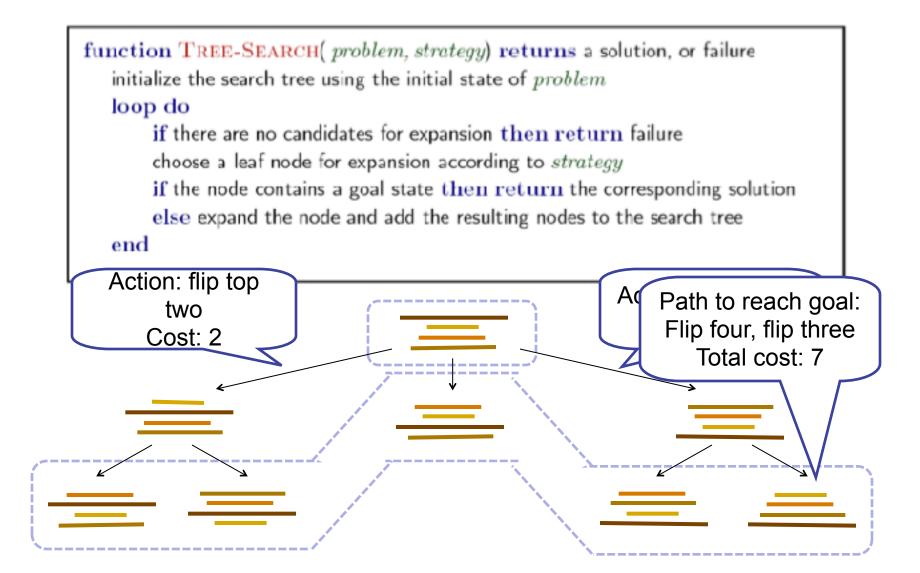

For a permutation σ of the integers from 1 to *n*, let $f(\sigma)$ be the smallest number of prefix reversals that will transform σ to the identity permutation, and let f(n) be the largest such $f(\sigma)$ for all σ in (the symmetric group) S_n . We show that $f(n) \leq (5n+5)/3$, and that $f(n) \geq 17n/16$ for *n* a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey $3n/2 - 1 \leq g(n) \leq 2n + 3$.

Example: Pancake Problem

State space graph with costs as weights

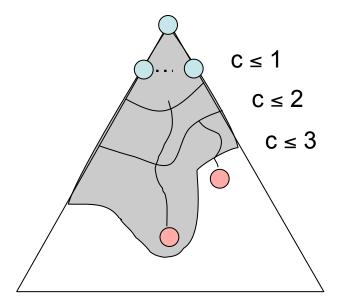

General Tree Search

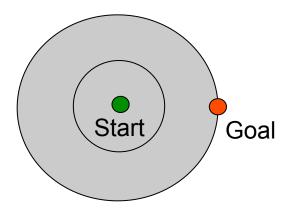

Uniform Cost Search

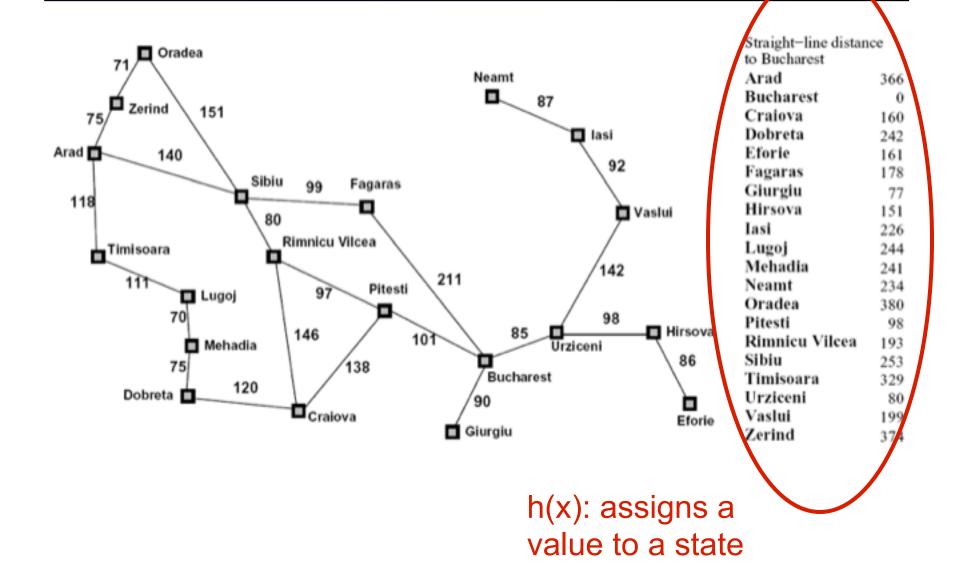

- Strategy: expand lowest path cost
- The good: UCS is complete and optimal!

- The bad:
 - Explores options in every "direction"
 - No information about goal location

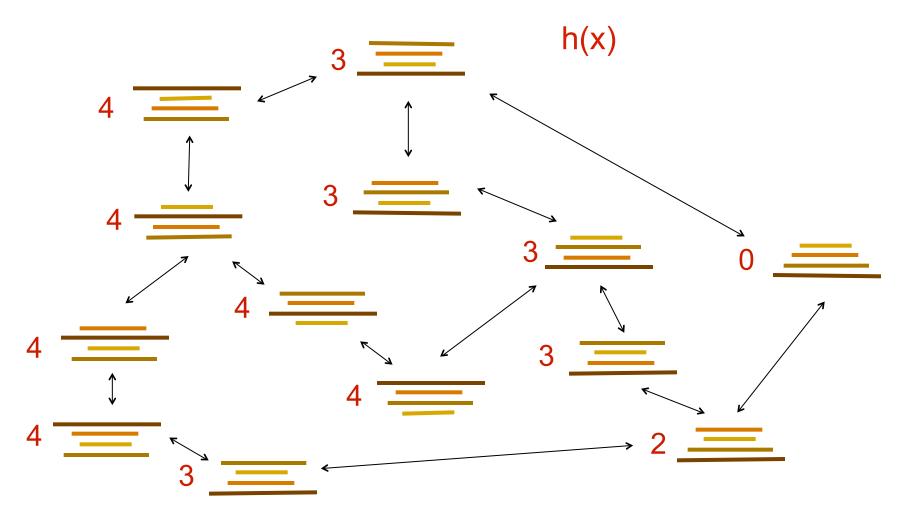

Example: Heuristic Function

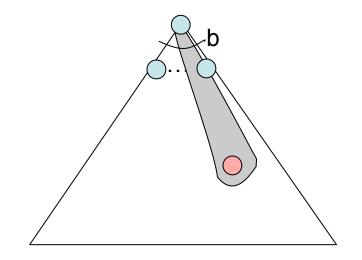

Example: Heuristic Function

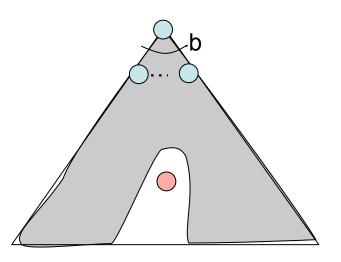

Heuristic: the largest pancake that is still out of place

Best First (Greedy)

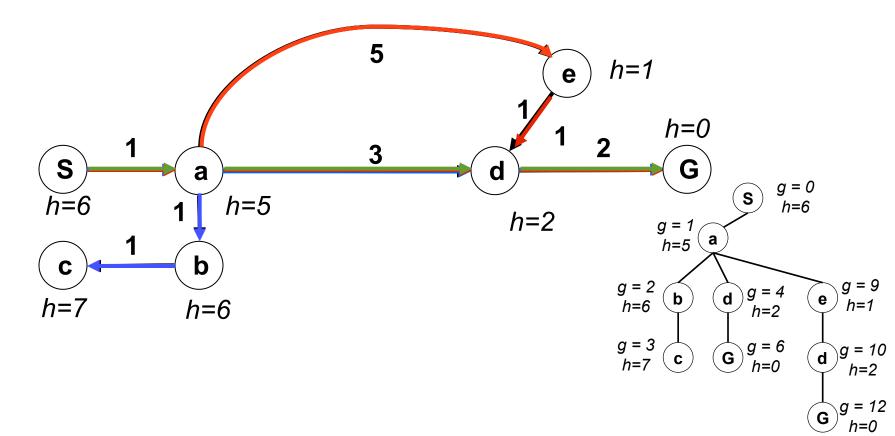

- Strategy: expand a node that you think is closest to a goal state
 - Heuristic: estimate of distance to nearest goal for each state
- A common case:
 - Best-first takes you straight to the (wrong) goal
- Worst-case: like a wrongly-guided DFS

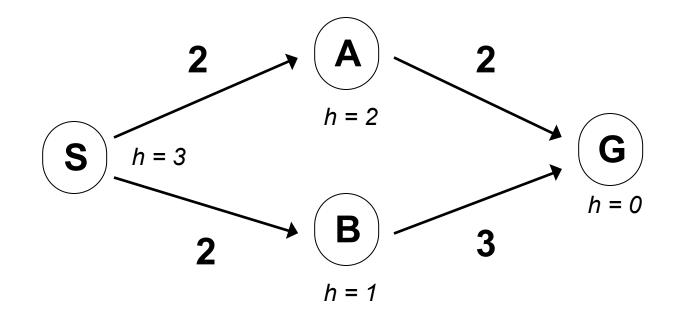

Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost f(n)=g(n)
- Best-first orders by goal proximity, or *forward cost* f(n)=h(n)
- A* Search orders by the sum: f(n) = g(n) + h(n)

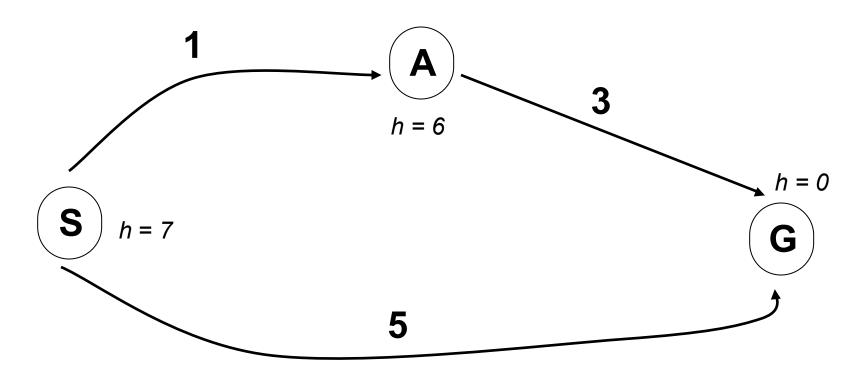

When should A* terminate?

Should we stop when we enqueue a goal?

No: only stop when we dequeue a goal

Is A* Optimal?

- What went wrong?
- Actual bad goal cost < estimated good goal cost</p>
- We need estimates to be less than actual costs!

Admissible Heuristics

• A heuristic *h* is *admissible* (optimistic) if:

 $h(n) \leq h^*(n)$

where $h^*(n)$ is the true cost to a nearest goal

 Coming up with admissible heuristics is most of what's involved in using A* in practice.

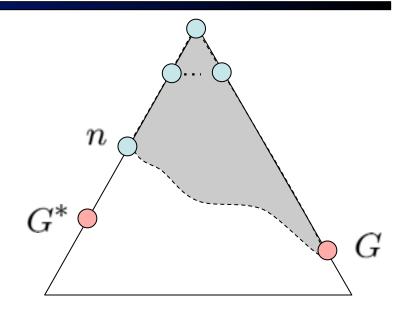

Optimality of A*

Assume:

- G* is an optimal goal
- G is a sub-optimal goal
- h is admissible

Claim:

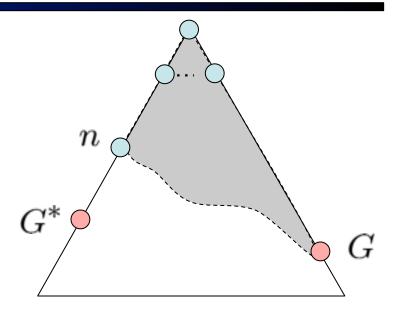

G* will exit fringe before G

Optimality of A*: Blocking

Notation:

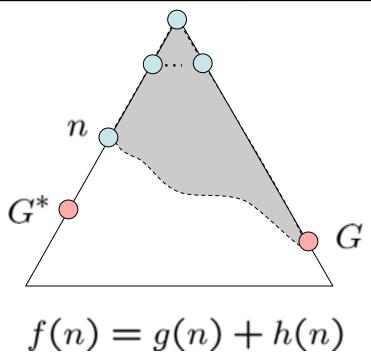

- g(n) = cost to node n
- h(n) = estimated cost from n to the nearest goal (heuristic)
- f(n) = g(n) + h(n) =
 estimated total cost via n
- G*: a lowest cost goal node
- G: another goal node

Optimality of A*: Blocking

Proof:

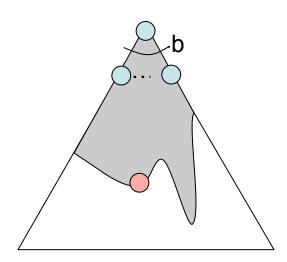

- What could go wrong?
- We'd have to have to pop a suboptimal goal G off the fringe before G*
- This can't happen:
 - For all nodes *n* on the best path to G*
 f(n) < f(G)
 - So, G* will be popped before G

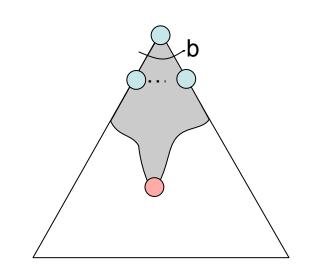

$$g(n) + h(n) \le g(G^*)$$
$$g(G^*) < g(G)$$
$$g(G) = f(G)$$
$$f(n) < f(G)$$

Properties of A*

Uniform-Cost

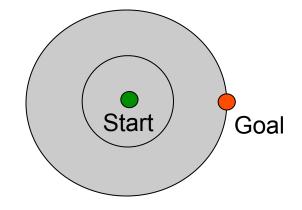

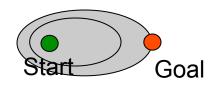

A*

UCS vs A* Contours

 Uniform-cost expanded in all directions

 A* expands mainly toward the goal, but does hedge its bets to ensure optimality

UCS

900 States

21

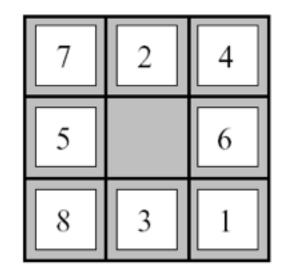

Astar

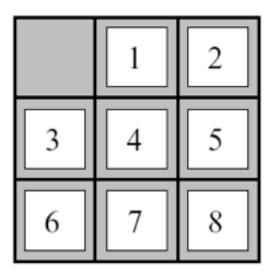

180 States

22

Creating Heuristics

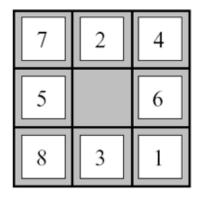

- What are the states?
- How many states?

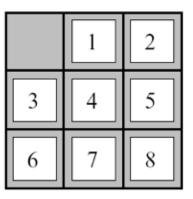

8-puzzle:

- What are the actions?
- What states can I reach from the start state?
- What should the costs be?

8 Puzzle I

 Heuristic: Number of tiles misplaced

Start State

Goal State

Is it admissible?

h(start) = 8

	Average nodes expanded when optimal path has length			
	4 steps	8 steps	12 steps	
UCS	112	6,300	3.6 x 10	
TILES	13	39	227	

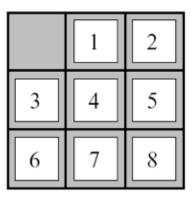

8 Puzzle II

- What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?
- Total Manhattan distance
- h(start) =
 - 3 + 1 + 2 + ...

= 18

Admissible?

Start State

Goal	State
------	-------

	Average nodes expanded when optimal path has length			
	4 steps	8 steps	12 steps	
TILES	13	39	227	
MANHATTAN	12	25	73	

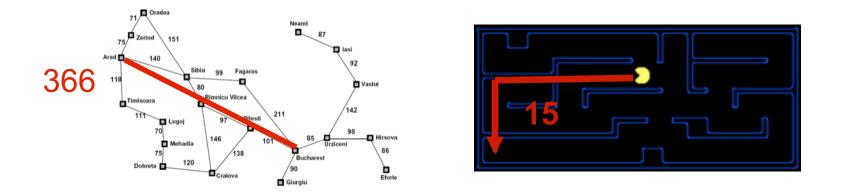

8 Puzzle III

- How about using the actual cost as a heuristic?
 - Would it be admissible?
 - Would we save on nodes expanded?
 - What's wrong with it?

With A*: a trade-off between quality of estimate and work per node!

Creating Admissible Heuristics

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to relaxed problems, where new actions are available

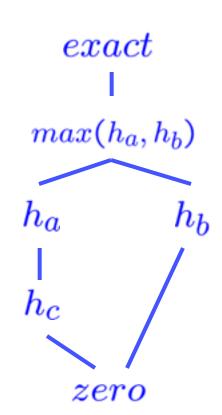

Inadmissible heuristics are often useful too (why?)

Trivial Heuristics, Dominance

- Dominance: $h_a \ge h_c$ if $\forall n : h_a(n) \ge h_c(n)$
- Heuristics form a semi-lattice:
 - Max of admissible heuristics is admissible $h(n) = max(h_a(n), h_b(n))$

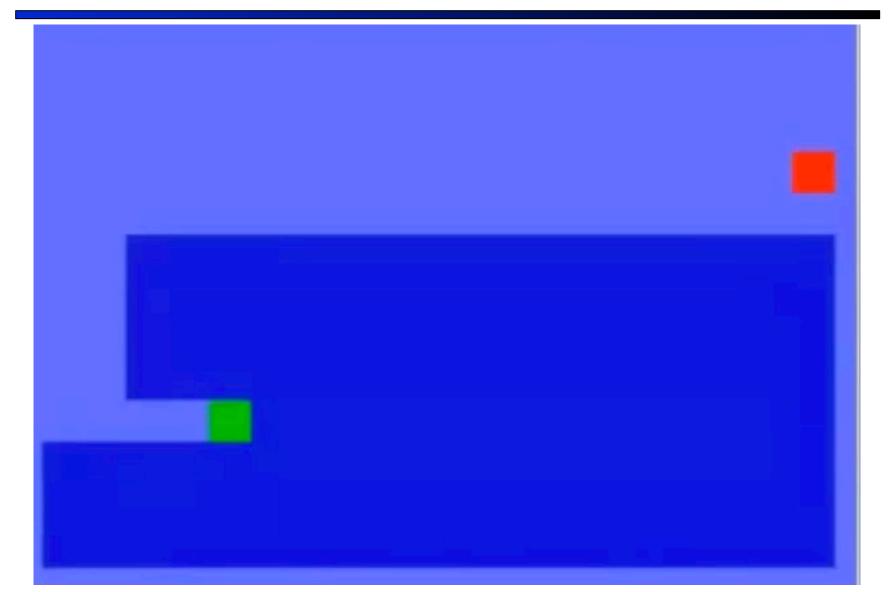

Trivial heuristics

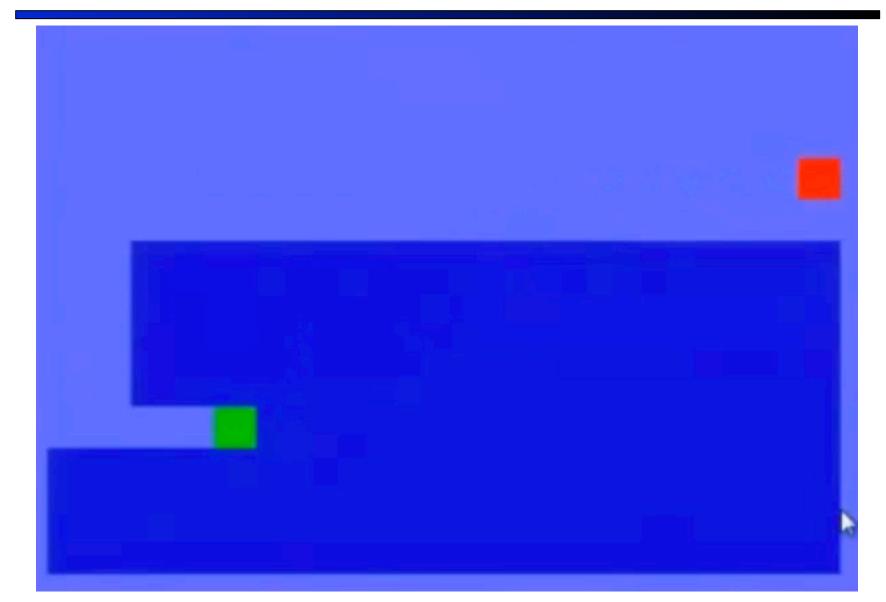

- Bottom of lattice is the zero heuristic (what does this give us?)
- Top of lattice is the exact heuristic

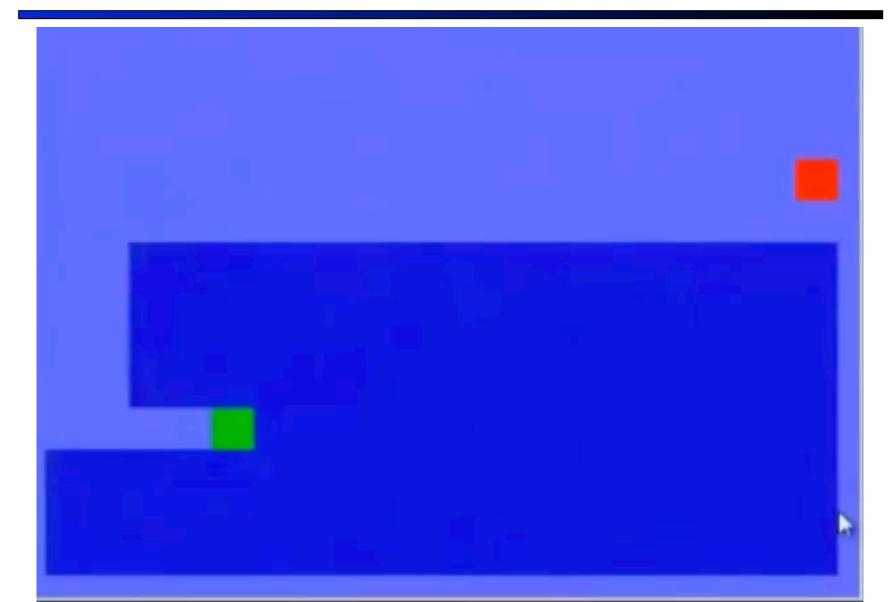

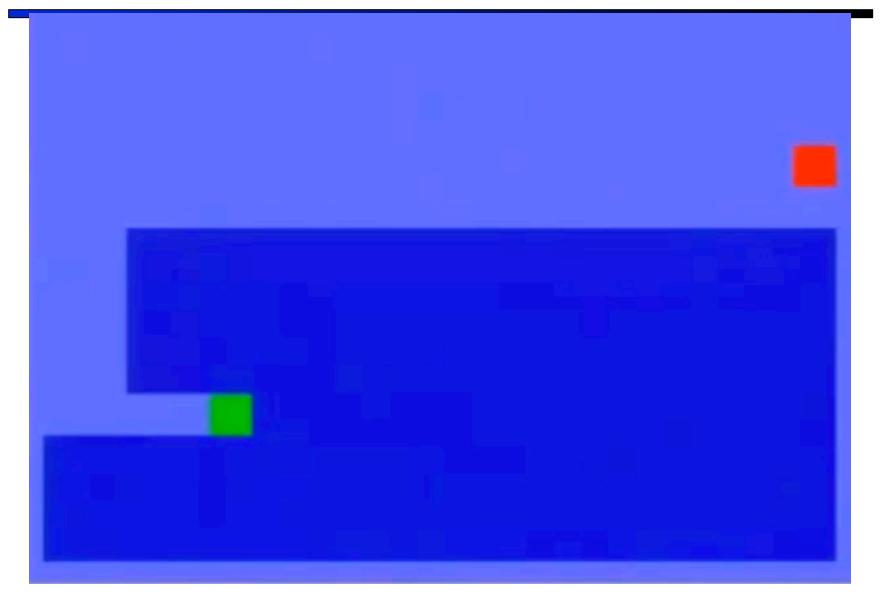

Today

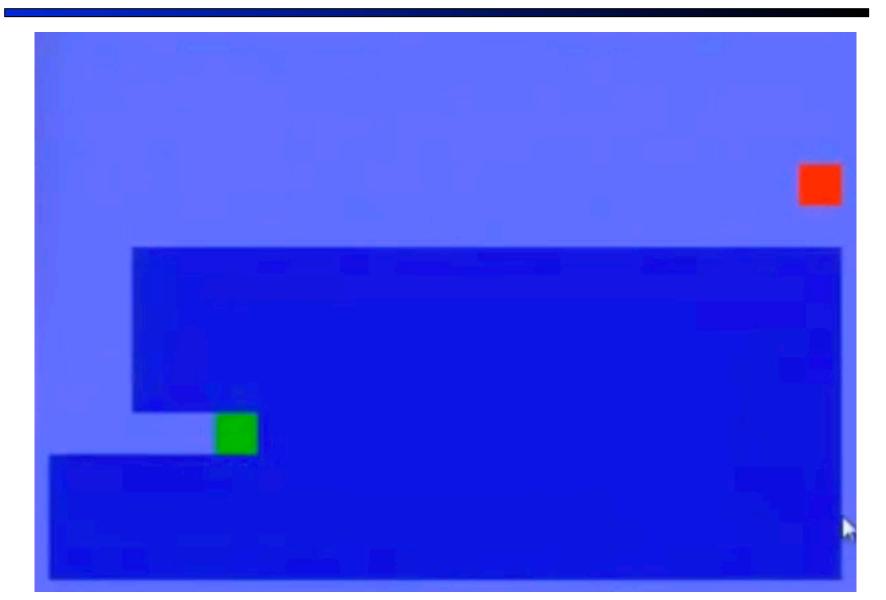

- Graph Search
 - Optimality of A* graph search
- Adversarial Search

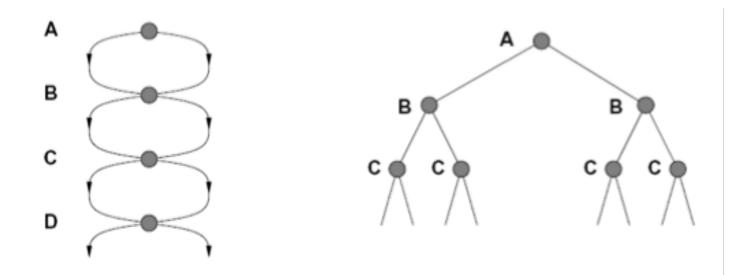

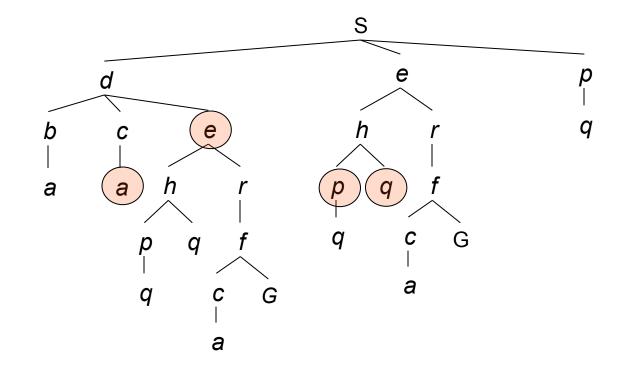

Tree Search: Extra Work!

Failure to detect repeated states can cause exponentially more work. Why?

Graph Search

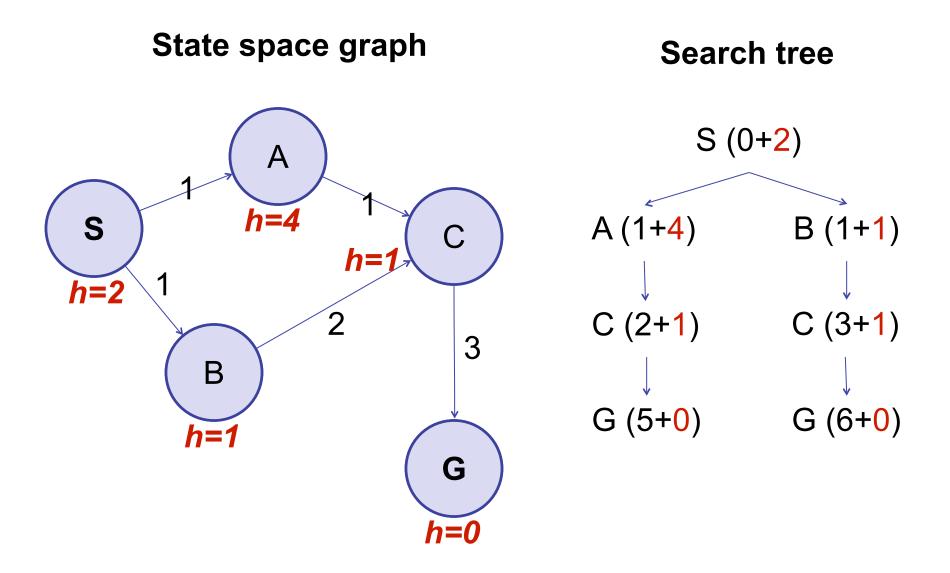

In BFS, for example, we shouldn't bother expanding some nodes (which, and why?)

Graph Search

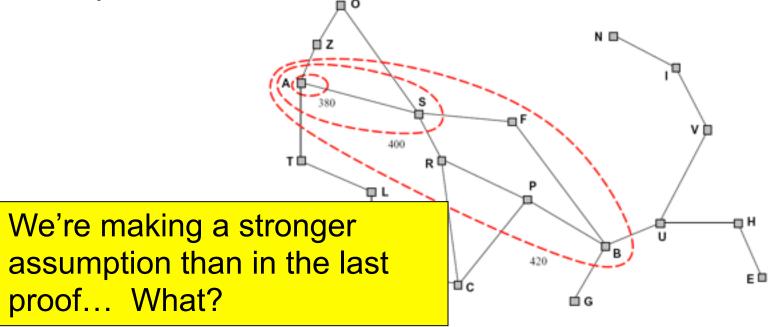

- Idea: never expand a state twice
- How to implement:
 - Tree search + list of expanded states (closed list)
 - Expand the search tree node-by-node, but...
 - Before expanding a node, check to make sure its state is new
 - Python trick: store the closed list as a set, not a list
 - Can graph search wreck completeness? Why/why not?
 - How about optimality?

A* Graph Search Gone Wrong

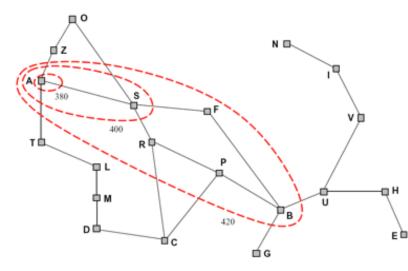

Consider what A* does:

- Expands nodes in increasing total f value (f-contours)
- Proof idea: optimal goals have lower f value, so get expanded first

Proof:

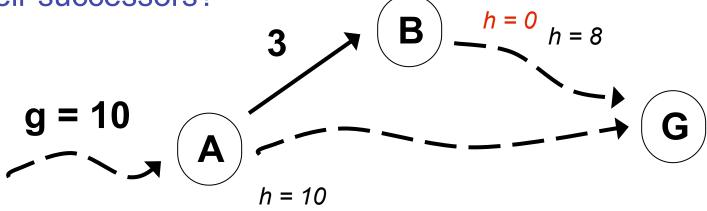

- Main idea: Show nodes are popped with non-decreasing f-scores
 - for n' popped after n :
 - $f(n') \ge f(n)$
 - is this enough for optimality?

- Sketch:
- assume: $f(n') \ge f(n)$, for all edges (n,a,n') and all actions a
 - is this true?
- proof: A* never expands nodes with the cost f(n)>C*
- proof by induction(1) always pop the lowest f-score from the fringe, (2) all new nodes have larger (or equal) scores, (3) add them to the fringe, (4) repeat!

Consistency

Wait, how do we know parents have better f-values than their successors?

- Consistency for all edges (A,a,B):
 h(A) ≤ c(A,a,B) + h(B)
- Proof that $f(B) \ge f(A)$,
 - f(B) = g(B) + h(B) = g(A) + c(A,a,B) + h(B) ≥ g(A) + h(A)= f(A)

Optimality

Tree search:

- A* optimal if heuristic is admissible (and nonnegative)
- UCS is a special case (h = 0)
- Graph search:
 - A* optimal if heuristic is consistent
 - UCS optimal (h = 0 is consistent)
- Consistency implies admissibility
- In general, natural admissible heuristics tend to be consistent

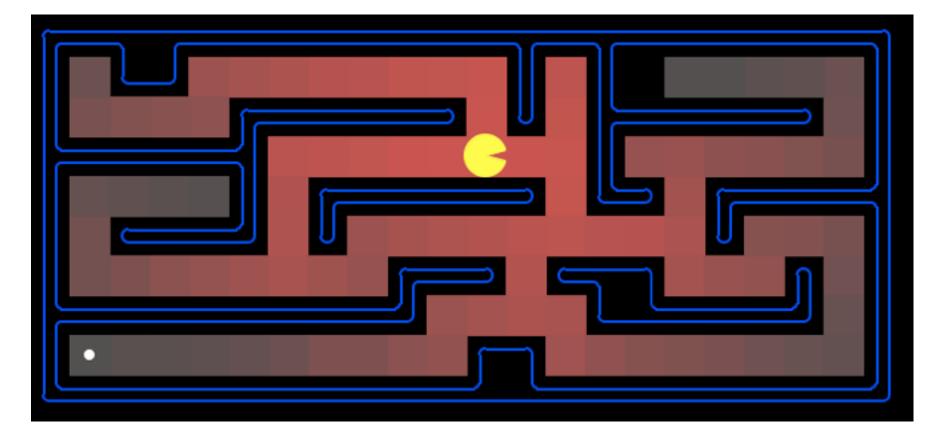

Summary: A*

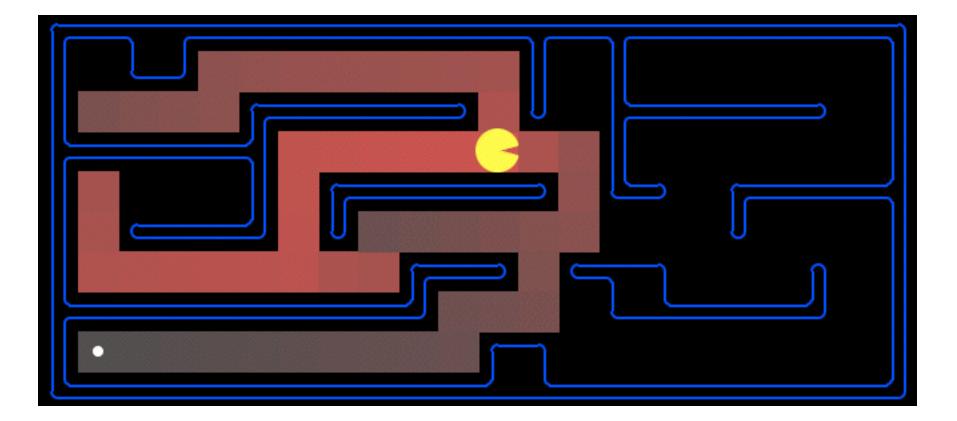

- A* uses both backward costs and (estimates of) forward costs
- A* is optimal with admissible (and/or consistent) heuristics
- Heuristic design is key: often use relaxed problems

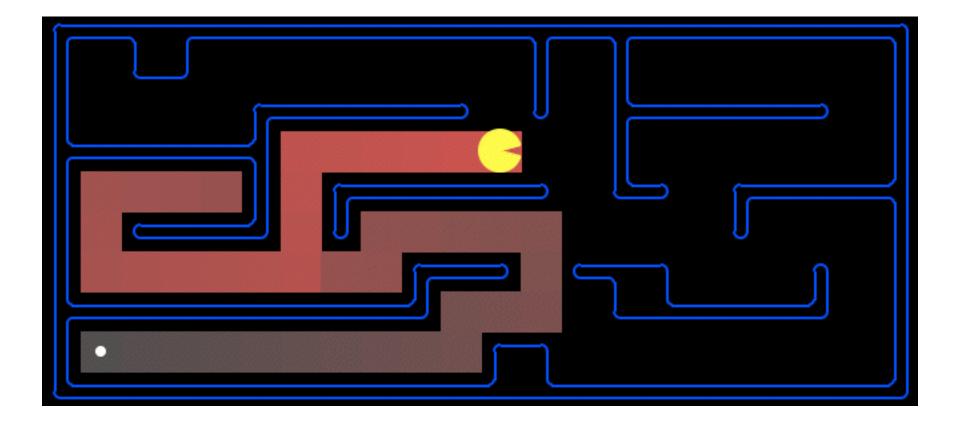

A* Applications

- Pathing / routing problems
- Resource planning problems
- Robot motion planning
- Language analysis
- Machine translation
- Speech recognition

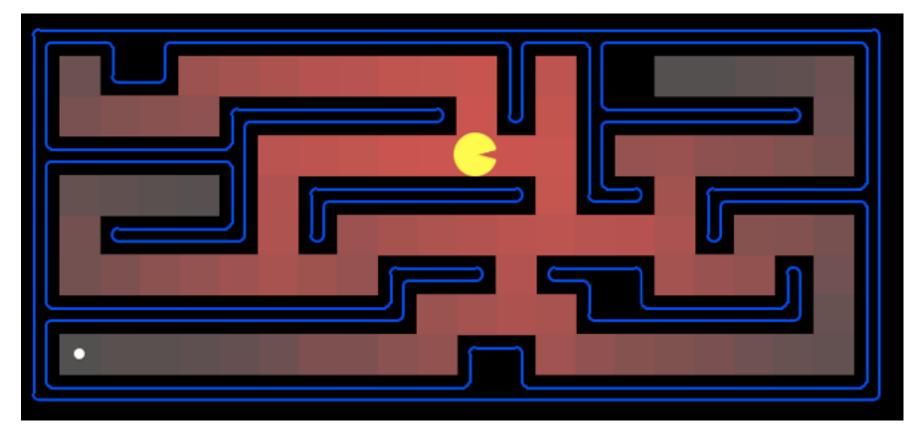

. . .

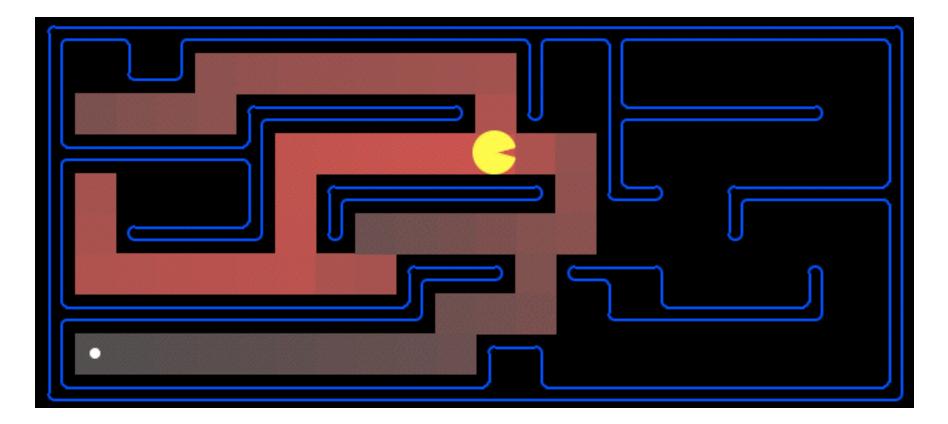

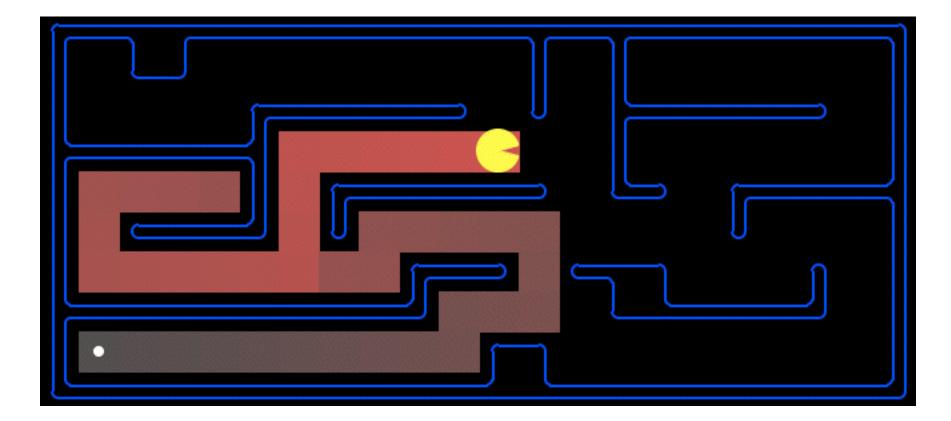

Uniform cost search (UCS):

• A*, Manhattan Heuristic:

Best First / Greedy, Manhattan Heuristic:

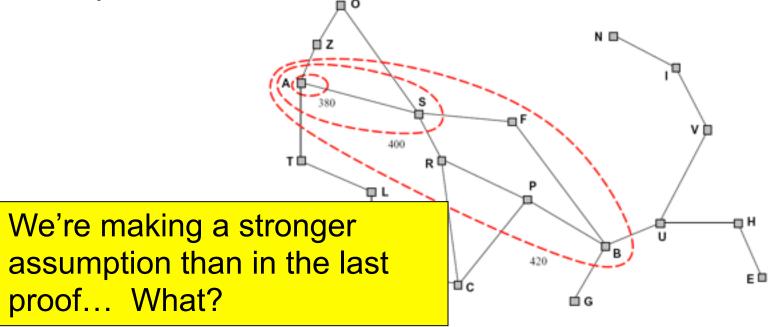

To Do:

Keep up with the readings
Get started on PS1
it is long; start soon

due a week from Friday

Consider what A* does:

- Expands nodes in increasing total f value (f-contours)
- Proof idea: optimal goals have lower f value, so get expanded first

Consider what A* does:

- Expands nodes in increasing total f value (f-contours) Reminder: f(n) = g(n) + h(n) = cost to n + heuristic
- Proof idea: the optimal goal(s) have the lowest f value, so it must get expanded first

There's a problem with this argument. What are we assuming is true?
