#### **Machine Translation**

#### Yejin Choi

Slides from Dan Klein, Luke Zettlemoyer, Dan Jurafsky, Ray Mooney

## Translation: Codebreaking?

When I look at an article in Russian, I say: 'This is really written in English, but it has been coded in some strange symbols. I will now proceed to decode.'

Warren Weaver (1955:18, quoting a letter he wrote in 1947)

# **Brief History of NLP**

- Mid 1950's mid 1960's: Birth of NLP and Linguistics
  - At first, people thought MT would be easy! Researchers predicted that "machine translation" can be solved in 3 years or so.
- Mid 1960's Mid 1970's: A Dark Era
  - People started believing that machine translation is impossible.
- 1970's and early 1980's Slow Revival of NLP
  - Small toy problems, linguistic heavy, weak empirical evaluation
- Late 1980's and 1990's Statistical Revolution!
  - By this time, the computing power increased substantially.
  - Data-driven, statistical approaches with simple representation.

→ "Whenever I fire a linguist, our MT performance improves." (Jelinek, 1988)

- 2000's Statistics Powered by Linguistic Insights
  - More complex statistical models & richer linguistic representations.

## Machine Translation: Examples

#### Atlanta, preso il killer del palazzo di Giustizia

ATLANTA - La grande paura che per 26 ore ha attanagliato Atlanta è finita: Brian Nichols, l'uomo che aveva ucciso tre persone a palazzo di Giustizia e che

ha poi ucciso un agente di dogana, s'è consegnato alla polizia, dopo avere cercato rifugio nell'alloggio di una donna in un complesso d'appartamenti alla periferia della città. Per tutto il giorno, il centro della città, sede della Coca Cola e dei Giochi 1996, cuore di una popolosa area metropolitana, era rimasto paralizzato.

#### Atlanta, taken the killer of the palace of Justice

ATLANTA - The great fear that for 26 hours has gripped Atlanta is ended: Brian Nichols, the man who had killed three persons to palace of Justice and that

a customs agent has then killed, s' is delivered to the police, after to have tried shelter in the lodging of one woman in a complex of apartments to the periphery of the city. For all the day, the center of the city, center of the Coke Strains and of Giochi 1996, heart of one popolosa metropolitan area, was remained paralyzed.

#### **Corpus-Based MT**

Modeling correspondences between languages

Sentence-aligned parallel corpus:

#### Levels of Transfer

## **General Approaches**

- Rule-based approaches
  - Expert system-like rewrite systems
  - Interlingua methods (analyze and generate)
  - Lexicons come from humans
  - Can be very fast, and can accumulate a lot of knowledge over time (e.g. Systran)
- Statistical approaches
  - Word-to-word translation
  - Phrase-based translation
  - Syntax-based translation (tree-to-tree, tree-to-string)
  - Trained on parallel corpora
  - Usually noisy-channel (at least in spirit)

#### Translation is hard!

zi	zhu	zhong	duan
自	助	终	端

#### self help terminal device

help oneself terminating machine

**Examples from Liang Huang** 

2

#### Translation is hard!

#### Translation is hard!

#### or even...

4

#### Human Evaluation

Madame la présidente, votre présidence de cette institution a été marquante. Mrs Fontaine, your presidency of this institution has been outstanding. Madam President, president of this house has been discoveries. Madam President, your presidency of this institution has been impressive.

Je vais maintenant m'exprimer brièvement en irlandais. I shall now speak briefly in Irish . I will now speak briefly in Ireland . I will now speak briefly in Irish .

Nous trouvons en vous un président tel que nous le souhaitions. We think that you are the type of president that we want. We are in you a president as the wanted. We are in you a president as we the wanted.

#### **Evaluation Questions:**

- Are translations fluent/grammatical?
- Are they adequate (you understand the meaning)?

# **MT: Automatic Evaluation**

- Human evaluations: subject measures, fluency/adequacy
- Automatic measures: n-gram match to references
  - NIST measure: n-gram recall (worked poorly)
  - BLEU: n-gram precision (no one really likes it, but everyone uses it)

#### BLEU:

- P1 = unigram precision
- P2, P3, P4 = bi-, tri-, 4-gram precision
- Weighted geometric mean of P1-4
- Brevity penalty (why?)
- Somewhat hard to game...

#### Reference (human) translation:

The U.S. island of Guam is maintaining a high state of alert <u>after the</u> Guam <u>airport and its</u> offices both received an e-mail from someone calling himself the Saudi Arabian Osama bin Laden and hreatening a biological/ chemical attack against public places such as <u>the airport</u>.

#### Machine ranslation:

The American [?] international airport and its the office all receives one calls self the sand Arab rich business [?] and so on electronic mail, which sends out; The threat will be able after public place and so on <u>the airport</u> to start the biochemistry attack, [?] highly alerts <u>after the</u> maintenance.

# Automatic Metrics Work (?)

Human Judgments

slide from G. Doddington (NIST)

### **MT System Components**

#### Part I – Word Alignment Models

#### Word Alignment

#### X

What is the anticipated cost of collecting fees under the new proposal?

En vertu des nouvelles propositions, quel est le coût prévu de perception des droits?

# Word Alignment

) Align words with a probabilistic model

) Infer presence of larger structures from this alignment

2

Translate with the larger structures

# **Unsupervised Word Alignment**

Input: a *bitext*, pairs of translated sentences

- Output: *alignments*: pairs of translated words
  - When words have unique sources, can represent as a (forward) alignment function a from French to English positions

## The IBM Translation Models

#### [Brown et al 1993]

#### The Mathematics of Statistical Machine Translation: Parameter Estimation

Peter F. Brown\* IBM T.J. Watson Research Center

Vincent J. Della Pietra\* IBM T.J. Watson Research Center Stephen A. Della Pietra\* IBM T.J. Watson Research Center

Robert L. Mercer\* IBM T.J. Watson Research Center

We describe a series of five statistical models of the translation process and give algorithms for estimating the parameters of these models given a set of pairs of sentences that are translations of one another. We define a concept of word-by-word alignment between such pairs of sentences. For any given pair of such sentences each of our models assigns a probability to each of the possible word-by-word alignments. We give an algorithm for seeking the most probable of these alignments. Although the algorithm is suboptimal, the alignment thus obtained accounts well for the word-by-word relationships in the pair of sentences. We have a great deal of data in French and English from the proceedings of the Canadian Parliament. Accordingly, we have restricted our work to these two languages; but we feel that because our algorithms have minimal linguistic content of our algorithms, that it is reasonable to argue that word-by-word alignments are inherent in any sufficiently large bilingual corpus.

# IBM Model 1 (Brown 93)

- Peter F. Brown, Vincent J. Della Pietra, Stephen A. Della Pietra, Robert L. Mercer
- The mathematics of statistical machine translation: Parameter estimation. In: Computational Linguistics 19 (2), 1993.
- 3667 citations.

Vincent (left) and Stephen Della Pietra

# IBM Model 1 (Brown 93)

- Model parameters: t(f|e) := p('e' is translated into 'f'|e)
- A (hidden) alignment vector  $(a_1, ..., a_m)$  where  $a_i = j$  means '*i* 'th target word is translated from '*j* 'th source word.
- Include a "null" word on the source side
- This alignment vector defines 1-to-many mappings. (why?) NULL<sub>0</sub> And<sub>1</sub> the<sub>2</sub> program<sub>3</sub> has<sub>4</sub> been<sub>5</sub> implemented<sub>6</sub>

i=1

$$p(f_1 \dots f_m, a_1 \dots a_m | e_1 \dots e_l, m) = \prod_{i=1}^m q(a_i | i, l, m) t(f_i | e_{a_i})$$
  
Uniform alignment model!
$$= \prod_{i=1}^m \frac{1}{l+1} t(f_i | e_{a_i})$$

## **IBM Model 1: Learning**

k i s.t.  $e_i = e_j$  s.t.  $f_i = f_j$ 

- If given data with alignment {( $e_1...e_l, a_1...a_m, f_1...f_m$ )<sub>k</sub>|k=1..n}  $t_{ML}(f|e) = \frac{c(e, f)}{c(e)}$  where  $\begin{array}{c} \delta(k, i, j) = 1 \text{ if } a_i^{(k)} = j, \ 0 \text{ otherwise} \\ c(e, f) = \sum \sum \sum \delta(k, i, j) \end{array}$
- In practice, no such data available at large scale.
- Thus, learn the translation model parameters while keeping alignment as latent variables, using EM,
  - Repeatedly re-compute the expected counts:

$$\delta(k, i, j) = \frac{t(f_i^{(k)} | e_j^{(k)})}{\sum_{j'} t(f_i^{(k)} | e_{j'}^{(k)})}$$

- Basic idea: compute expected source for each word, update cooccurrence statistics, repeat
- Q: What about inference? Is it hard?

#### Sample EM Trace for Alignment (IBM Model 1 with no NULL Generation)

#### Example cont.

green house green house the house the house casa verde casa verde la casa la casa 1/2 1/2 1/2 1/2 verde la casa Compute green 1/21/20 weighted house 1/21/2 + 1/21/2translation 1/2 1/2the 0 counts verde la casa Normalize green 1/21/20 rows to sum house 1/41/21/4to one to the | estimate P(f | e) 0 1/21/2

#### Example cont.

Continue EM iterations until translation parameters converge

#### IBM Model 1 - EM intuition

Example from Philipp Koehn

# **Evaluating Alignments**

- How do we measure quality of a word-to-word model?
  - Method 1: use in an end-to-end translation system
    - Hard to measure translation quality
    - Option: human judges
    - Option: reference translations (NIST, BLEU)
    - Option: combinations (HTER)
    - Actually, no one uses word-to-word models alone as TMs
  - Method 2: measure quality of the alignments produced
    - Easy to measure
    - Hard to know what the gold alignments should be
    - Often does not correlate well with translation quality (like perplexity in LMs)

### **Alignment Error Rate**

#### Alignment Error Rate

- A := predicted alignments
- S := sure alignments
- P := possible alignments (including sure alignments)

$$AER(A, S, P) = \left(1 - \frac{|A \cap S| + |A \cap P|}{|A| + |S|}\right)$$
$$= \left(1 - \frac{3 + 3}{3 + 4}\right) = \frac{1}{7}$$

# Problems with Model 1

- There's a reason they designed models 2-5!
- Problems: alignments jump around, align everything to rare words
- Experimental setup:
  - Training data: 1.1M sentences of French-English text, Canadian Hansards
  - Evaluation metric: alignment error Rate (AER)
  - Evaluation data: 447 handaligned sentences

### **Intersected Model 1**

- Post-intersection: standard practice to train models in each direction then intersect their predictions [Och and Ney, 03]
- Second model is basically a filter on the first
  - Precision jumps, recall drops
  - End up not guessing hard alignments

Model	P/R	AER
Model 1 E→F	82/58	30.6
Model 1 F→E	85/58	28.7
Model 1 AND	96/46	34.8

# Joint Training?

- "Alignment by agreement" (Liang et al, 2006)
  - Similar high precision to post-intersection
  - But recall is much higher
  - More confident about positing non-null alignments

Model	P/R	AER
Model 1 E→F	82/58	30.6
Model 1 F→E	85/58	28.7
Model 1 AND	96/46	34.8
Model 1 INT	93/69	19.5

#### **Monotonic Translation**

# Japan shaken by two new quakes

#### Local Order Change

# Japan is at the junction of four tectonic plates

# IBM Model 2 (Brown 93)

 Alignments: a hidden vector called an *alignment* specifies which English source is responsible for each French target word.

 Same decomposition as Model 1, but we will use a multi-nomial distribution for q!

## IBM Model 2: Learning

• Given data {( $e_1...e_l, a_1...a_m, f_1...f_m$ )<sub>k</sub>|k=1..n} where  $t_{ML}(f|e) = \frac{c(e,f)}{c(e)} \quad q_{ML}(j|i,l,m) = \frac{c(j|i,l,m)}{c(i,l,m)} \quad \begin{array}{l} \delta(k,i,j) = 1 \text{ if } a_i^{(k)} = j, \ 0 \text{ otherwise} \\ c(e,f) = \sum_k \sum_{i \text{ s.t. } e_i = e} \sum_{j \text{ s.t. } f_j = f} \delta(k,i,j) \end{array}$ 

- Better approach: re-estimated generative models with EM,
  - Repeatedly compute counts, using redefined deltas:

$$\delta(k, i, j) = \frac{q(j|i, l_k, m_k)t(f_i^{(k)}|e_j^{(k)})}{\sum_{j'} q(j'|i, l_k, m_k)t(f_i^{(k)}|e_{j'}^{(k)})}$$

- Basic idea: compute expected source for each word, update co-occurrence statistics, repeat
- Q: What about inference? Is it hard?

#### Example

#### Phrase Movement

Des tremblements de terre ont à nouveau touché le Japon jeudi 4 novembre.

## The HMM Model

# The HMM Model

- Model 2 can learn complex alignments
- We want local monotonicity:
  - Most jumps are small
- HMM model (Vogel 96)

	f	$t(f \mid e)$
ſ	nationale	0.469
	national	0.418
	nationaux	0.054
	nationales	0.029

$$P(f, a|e) = \prod_{j} P(a_{j}|a_{j-1})P(f_{j}|e_{i})$$

$$P(a_{j} - a_{j-1}) \longrightarrow \square \square \square$$

$$-2 - 1 \ 0 \ 1 \ 2 \ 3$$

- Re-estimate using the forward-backward algorithm
- Handling nulls requires some care
- What are we still missing?

#### **HMM Examples**

Phrase table (translation model)

## Phrase Translation Tables

- Defines the space of possible translations
  - each entry has an associated "probability"
- One learned example, for "den Vorschlag" from Europarl data

English	$\phi(ar{e} ar{f})$	English	$\phi(ar{e} ar{f})$
the proposal	0.6227	the suggestions	0.0114
's proposal	0.1068	the proposed	0.0114
a proposal	0.0341	the motion	0.0091
the idea	0.0250	the idea of	0.0091
this proposal	0.0227	the proposal,	0.0068
proposal	0.0205	its proposal	0.0068
of the proposal	0.0159	it	0.0068
the proposals	0.0159		

 This table is noisy, has errors, and the entries do not necessarily match our linguistic intuitions about consistency....

### **Extracting Phrases**

We will use word alignments to find phrases

Question: what is the best set of phrases?

# **Extracting Phrases**

#### Phrase alignment must

- Contain at least one alignment edge
- Contain all alignments for phrase pair

Extract all such phrase pairs!

## Phrase Pair Extraction Example

(Maria, Mary), (no, did not), (slap, daba una bofetada), (a la, the), (bruja, witch), (verde, green) (Maria no, Mary did not), (no daba una bofetada, did not slap), (daba una bofetada a la, slap the), (bruja verde, green witch)

(Maria no daba una bofetada, Mary did not slap), (no daba una bofetada a la, did not slap the), (a la bruja verde, the green witch)

(Maria no daba una bofetada a la, Mary did not slap the), (daba una bofetada a la bruja verde, slap the green witch)

(Maria no daba una bofetada a la bruja verde, Mary did not slap the green witch)

#### Phrase Size

#### Phrases do help

 But they don't need to be long

Why should this be?

# Why not Learn Phrases w/ EM?

#### **EM Training of the Phrase Model**

- We presented a heuristic set-up to build phrase translation table (word alignment, phrase extraction, phrase scoring)
- Alternative: align phrase pairs directly with EM algorithm
  - initialization: uniform model, all  $\phi(\bar{e},\bar{f})$  are the same
  - expectation step:
    - \* estimate likelihood of all possible phrase alignments for all sentence pairs
  - maximization step:
    - \* collect counts for phrase pairs  $(\bar{e}, \bar{f})$ , weighted by alignment probability
    - \* update phrase translation probabilties  $p(\bar{e}, \bar{f})$
- However: method easily overfits (learns very large phrase pairs, spanning entire sentences)

# Phrase Scoring

- Learning weights has been tried, several times:
  - [Marcu and Wong, 02]
  - [DeNero et al, 06]
  - ... and others
- Seems not to work well, for a variety of partially understood reasons
- Main issue: big chunks get all the weight, obvious priors don't help
  - Though, [DeNero et al 08]

Table 1: #11# the seven - member crew includes a stronauts from france and russia .

# Scoring:

- Basic approach, sum up phrase translation scores and a language model
  - Define y = p<sub>1</sub>p<sub>2</sub>...p<sub>L</sub> to be a translation with phrase pairs p<sub>i</sub>
  - Define e(y) be the output English sentence in y
  - Let h() be the log probability under a tri-gram language model
  - Let g() be a phrase pair score (from last slide)
  - Then, the full translation score is:

$$f(y) = h(e(y)) + \sum_{k=1}^{L} g(p_k)$$

Goal, compute the best translation

$$y^*(x) = \arg \max_{y \in \mathcal{Y}(x)} f(y)$$

#### The Pharaoh Decoder

	did_no	t give	L		<u>to</u>			
			sl	ар		the	witch	

Maria	no	dio una bofetada	a la	bruja	verde
Mary	did not	slap	the	green	witch

#### Scores at each step include LM and TM

#### The Pharaoh Decoder

#### Space of possible translations

- Phrase table constrains possible translations
- Output sentence is built left to right
  - but source phrases can match any part of sentence
- Each source word can only be translated once
- Each source word must be translated

# Scoring:

- In practice, much like for alignment models, also include a distortion penalty
  - Define  $y = p_1 p_2 \dots p_L$  to be a translation with phrase pairs  $p_i$
  - Let s(p<sub>i</sub>) be the start position of the foreign phrase
  - Let t(p<sub>i</sub>) be the end position of the foreign phrase
  - Define η to be the distortion score (usually negative!)
  - Then, we can define a score *with distortion penalty*:

$$f(y) = h(e(y)) + \sum_{k=1}^{L} g(p_k) + \sum_{k=1}^{L-1} \eta \times |t(p_k) + 1 - s(p_{k+1})|$$

Goal, compute the best translation

$$y^*(x) = \arg \max_{y \in \mathcal{Y}(x)} f(y)$$

## Hypothesis Expansion

- ... until all foreign words *covered* 
  - find best hypothesis that covers all foreign words
  - backtrack to read off translation

## Hypothesis Explosion!

- Q: How much time to find the best translation?
  - Exponentially many translations, in length of source sentence
  - NP-hard, just like for word translation models
  - So, we will use approximate search techniques!

# Hypothesis Lattices

Last two English words match

· Foreign word coverage vectors match

#### Decoder Pseudocode

Initialization: Set beam  $Q = \{q_0\}$  where  $q_0$  is initial state with no words translated

For i=0 ... n-1 [where n in input sentence length] •For each state  $q \in beam(Q)$  and phrase  $p \in ph(q)$ 

- 1. q'=next(q,p) [compute the new state]
- 2. Add(Q,q',q,p)

[add the new state to the beam]

Notes:

•ph(q): set of phrases that can be added to partial translation in state q

 next(q,p): updates the translation in q and records which words have been translated from input

•Add(Q,q',q,p): updates beam, q' is added to Q if it is in the top-n overall highest scoring partial translations

#### Decoder Pseudocode

Initialization: Set beam  $Q = \{q_0\}$  where  $q_0$  is initial state with no words translated

For i=0 ... n-1[where n in input sentence length]•For each state q $\in$  beam(Q) and phrase p $\in$  ph(q)1. q'=next(q,p)2. Add(Q,q',q,p)[add the new state to the beam]

Possible State Representations:

•Full:  $q = (e, b, \alpha)$ , e.g. ("Joe did not give," 11000000, 0.092)

- e is the partial English sentence
- b is a bit vector recorded which source words are translated
- α is score of translation so far
## Decoder Pseudocode

Initialization: Set beam  $Q = \{q_0\}$  where  $q_0$  is initial state with no words translated

For i=0 ... n-1[where n in input sentence length]•For each state q $\in$  beam(Q) and phrase p $\in$  ph(q)1. q'=next(q,p)2. Add(Q, g', g, g)

2. Add(Q,q',q,p) [add the new state to the beam]

Possible State Representations:

•Full:  $q = (e, b, \alpha)$ , e.g. ("Joe did not give," 11000000, 0.092) •Compact:  $q = (e_1, e_2, b, r, \alpha)$ ,

- e.g. ("not," "give," 11000000, 4, 0.092)
- $e_1$  and  $e_2$  are the last two words of partial translation
- r is the length of the partial translation

•Compact representation is more efficient, but requires back pointers to get the final translation
