CSE 505: Concepts of Programming Languages

Dan Grossman
Fall 2009
Lecture 18— Bounded Polymorphism and Classless OOP
Revenge of Type Variables

Sorted lists in ML (partial):

```
type 'a slist
make : ('a -> 'a -> int) -> 'a slist
cons : 'a slist -> 'a -> 'a slist
find : 'a slist -> 'a -> 'a option
```

Getting by with OO subtyping:

```
interface Cmp { Int f(Object, Object); }
class SList {
    ... some field definitions ...
    constructor (Cmp x) {...}
    Slist cons(Object x) {...}
    Object find(Object x) {...}
}
```
Wanting Type Variables

Will downcast (potential run-time exception) the arguments to \( f \) and the result of \( \text{find} \).

We are not enforcing list-element type-equality.

OO-style subtyping is no replacement for parametric polymorphism; we can have both:

```java
interface 'a Cmp { Int f('a,'a); } // Cmp not a type
class 'a SList { // SList not a type (Int SList e.g. is)
    ... some field definitions (can use type 'a) ...
    constructor ('a Cmp x) {...}
    'a Slist cons('a x)   {...}
    'a                   find('a)   {...}
}
```
Same Old Story

- Interface and class declarations are *parameterized*; they produce types.
- The constructor is polymorphic
  - For all $T$, given a $T$ `Cmp`, it makes a $T$ `SList`
- If $o$ has type $T$ `SList`, its `cons` method:
  - takes a $T$
  - returns a $T$ `SList`

No more downcasts; the best of both worlds.
Complications

“Interesting” interaction with overloading and multimethods

```java
class B {
    unit f(Int C x) {...}
    unit f(String C x) {...}
}
class 'a C { unit g(B x) { x.f(self); } }
```

For T C where T is neither Int nor String, can have no match

- Cannot resolve static overloading at compile-time without code duplication and no abstraction (C++)
- To resolve overloading or multimethods at run-time, need run-time type information *including the instantiation* T (C#)
- Could disallow such overloading (Java)
- Or could just reject this sort of call as unresolvable (?)
Wanting bounds

There are compelling reasons to *bound* the instantiation of type variables.

Simple example: Use at supertype without losing that it's a subtype

```java
interface I { unit print(); }
class ('a < I) Logger { // must apply to subtype of I
    'a item;
    'a get_it() { syslog(item.print()); item }
}
```

Without polymorphism or downcasting, client could only use `get_it` result for printing.

Without bound or downcasting, Logger could not print.
Fancy Example

With forethought and structural (non-named) subtyping, bounds can avoid some subtyping limitations.
(Example lifted from “A Theory of Objects” Abadi/Cardelli)

interface Omnivore { unit eat(Food); }
interface Herbivore { unit eat(Veg); } // Veg <= Food

Allowing Herbivore ≤ Omnivore could make a vegetarian eat meat (unsound)! But this works:

interface (’a < Food) Omnivore { unit eat(’a); }
interface (’a < Veg) Herbivore { unit eat(’a); }

If T Herbivore is legal, then T Omnivore is legal and (T Herbivore) ≤ (T Omnivore)!

Useful for unit feed(’a food, ’a Omnivore animal) {...}.
Bounded Polymorphism

This “bounded polymorphism” is useful in any language with universal types and subtyping. Instead of $\forall \alpha.\tau$ and $\Lambda \alpha.e$, we have $\forall \alpha < \tau'.\tau$ and $\Lambda \alpha < \tau'.e$:

- Change $\Delta$ to be a list of bounds ($\alpha < \tau$) instead of a set of type variables
- In $e$ you can subsume from $\alpha$ to $\tau'$
- $e_1[\tau_1]$ typechecks only if $\tau_1$ “satisfies the bound” in type of $e_1$

One metatheory drawback: When is $(\forall \alpha_1 < \tau_1.\tau_2) \leq (\forall \alpha_2 < \tau_3.\tau_4)$?

- Contravariant bounds and covariant bodies assuming bound are sound, but makes subtyping undecidable
- Requiring invariant bounds and covariant bodies regains decidability, but obviously allows less subtyping
Classless OOP

OOP gave us code-reuse via inheritance and extensibility via late-binding.

Can we throw out classes and still get OOP? Yes.

Can it have a type system that prevents “no match found” and “no best match” errors? Yes, but we won’t get there.

This is mind-opening stuff if you’ve never seen it.

*We will make up syntax as we go along...*
Make objects directly

Everything is an object. You can make objects directly:

let p = [
    field x = 7;
    field y = 9;
    right_quad() { x.gt(0) && y.gt(0) } // cf. 0.lte(y)
]

p now bound to an object: can invoke its methods and read/write its fields

No classes: Constructors are easy to encode

let make_pt = [
    doit(x0, y0) { [ field x=x0; field y=y0;... ] }
]
Inheritance and Override

Building objects from scratch won’t get us late-binding and code reuse. Here’s the trick:

- clone method produces a (shallow) copy of an object
- method “slots” can be mutable

```javascript
let o1 = [ // still have late-binding
  odd(x) {if x.eq(0) then false else self.even(x-1)}
  even(x) {if x.eq(0) then true else self.odd(x-1) }
]
let o2 = o1.clone()
o2.even(x) := (x.mod(2)).eq(0)
```

Language doesn’t grow: just methods and mutable “slots”

Can use for constructors too: clone and assign fields
Extension

But that trick doesn’t work to add slots to an object, a common use of subclassing.

Having something like “extend e1 (x=e2)” that mutates e1 to have a new slot is problematic semantically (what if e1 has a slot named x) and for efficiency (may not be room where e1 is allocated)

Instead, we can build a new object with a special parent slot:
[parent=e1; x=e2]

parent is very special because definition of method-lookup (the issue in OO) depends on it (else this isn’t inheritance)
Method Lookup

To find the $m$ method of $o$:

- Look for a slot named $m$
- If not found, look in object held in parent slot

But we still have late-binding: for method in parent slot, we still have self refer to the original $o$.

Two *inequivalent* ways to define parent=e1:

- Delegation: parent refers to result of e1
- Embedding: parent refers to result of e1.clone()

Mutation of result of e1 (or its parent or grandparent or ...) exposes the difference. We’ll assume delegation.
Oh so flexible

Delegation is way more flexible (and simple!) (and dangerous!) than class-based OO: The object being delegated to is usually used like a class, but its slots may be mutable.

- Assigning to a slot in a delegated object changes every object that delegates to it (transitively)
  - Clever change-propagation but as dangerous as globals and arguably more subtle?

- Assigning to a parent slot is “dynamic inheritance” — changes where slots are inherited from

Classes restrict what you can do and how you think, e.g., never thinking of clever run-time modifications of inheritance
Javascript: A Few Notes

- Javascript gives assignment “extension” semantics if field not already there. Implementations use indirection (hashtables).
- *parent* is called *prototype*.
- `new F(...)` creates a new object `o`, calls `F` with `this` bound to `o`, and returns `o`.
  - No special notion of constructor.
  - Functions are objects too.
  - This isn’t quite prototype-based inheritance, but can code it up:

```javascript
    function inheritFrom(o) {
        function F() {}
        F.prototype = o;
        return new F();
    }
```

- No clone (depending on version), but can copy fields explicitly
Rarely what you want

We have the essence of OOP in a tiny language with more flexibility than we usually want.

Avoid it via careful coding idioms:

- Create *trait/abstract* objects: Just immutable methods
  - Analogous role to virtual-method tables
- Extend with *prototype/template* objects: Add mutable fields but don’t mutate them
  - Analogous role to classes
- Clone prototypes to create *concrete/normal* objects
  - Analogous role to objects (clone is constructor)

Traits can extend other traits and prototypes other prototypes

- Analogous to subclassing
Coming full circle

Without separating first two roles, objects don’t share method slots (wastes space), but immutability avoids danger.

Late-binding still makes method-override work correctly.

This idiom is so important, it’s worth having a type system that enforces it.

For example, a template object cannot have its members accessed (except clone).

We end up getting close to classes, but from first principles and still allowing the full flexibility when you want it.
A word on types

Untyped languages work (the OO of Scheme) – may get a “no match found” exception at run-time. Very flexible.

But we can develop type systems that restrict the language and prevent getting stuck without developing a class system.

Can base types on “derived from the same object,” which can form the basis for multimethods.

• See Cecil (Chambers et al)

Summary: Pure classless OOP a liberating way to think, especially if you learn workarounds in more restrictive languages.
