But first, some clean up.

Our semantics:

- For a simple substitution rule:
  \[ e_1 \rightarrow e'_1 \]
  \[ e_1 \ e_2 \rightarrow e'_1 \ e'_2 \]
  \[ e \rightarrow e' \]
  \[ e \rightarrow e' \]

- For matching with substitution:
  \[ (e_1, e_2) \rightarrow (e'_1, e'_2) \]
  \[ (v_1, e_2) \rightarrow (v'_1, e'_2) \]
  \[ e.1 \rightarrow e'.1 \]
  \[ e.2 \rightarrow e'.2 \]

- For matching without substitution:
  \[ e \rightarrow e' \]

- For matching with a fresh variable:
  \[ (\lambda x. e) \ v \rightarrow e[v/x] \]
  \[ (v_1, v_2).1 \rightarrow v_1 \]
  \[ (v_1, v_2).2 \rightarrow v_2 \]

- For matching with a substitution:
  \[ \text{match } A(v) \text{ with } Ax. e_1 \mid By. e_2 \rightarrow e_1[v/x] \]
  \[ \text{match } B(v) \text{ with } Ay. e_1 \mid By. e_2 \rightarrow e_2[v/x] \]

GOTO the past / programs choose their own adventure.
We can do better: Separate concerns

Evaluation contexts define where interesting work can happen:

\[ E ::= [\cdot] | E \; e | v \; E | (E, e) | (v, E) | E.1 | E.2 \\
| A(E) | B(E) | (match \ E \ with \ A.\; e_1 \; | \; B.\; e_2) \]

Evaluation with evaluation contexts

\[ E := [\cdot] | E \; e | v \; E | (E, e) | (v, E) | E.1 | E.2 \\
| A(E) | B(E) | (match \ E \ with \ A.\; e_1 \; | \; B.\; e_2) \]

A given \( E \) just means to “fill the hole” in \( E \) with \( e \):

\[ ([\cdot], 1)((1, 2)) = (1, 2).1 \]

\[ ([\cdot], \lambda x.x)[1] = (1, \lambda x.x) \]

\[ ([\cdot \; x \; y])[(\lambda a. \lambda b. a)] = (\lambda a. \lambda b. a) \; x \; y \]

Many possible eval contexts may match a give \( e \) ...

\[ ([\cdot])[(1, (1, (1, 1)))) = (1, (1, (1, 1))) \]

\[ ((1, [\cdot]))[(1, (1, 1))] = (1, (1, (1, 1))) \]

\[ ((1, (1, [\cdot])))[(1, 1)) = (1, (1, (1, 1))) \]

\[ ((1, (1, (1, [\cdot])))][(1, 1)] = (1, (1, (1, 1))) \]

\[ ((1, (1, (1, [\cdot])))][(1, 1)] = (1, (1, (1, 1))) \]
Evaluation with evaluation contexts

\[
E ::= [\cdot] | E e | v E | (E, e) | (v, E) | E.1 | E.2 \\
| A(E) | B(E) | (match E with Ax. e_1 | By. e_2)
\]

Evaluation relies on \textit{decomposition} (unstapling the correct subtree)

- Given \( e \), find \( E, e_a, e'_a \) such that \( e = E[e_a] \) and \( e_a \xrightarrow{P} e'_a \)

\textit{Unique Decomposition Theorem}: at most one decomposition of \( e \)

- \( E \) carefully picks leftmost non-value sub-expression
- Hence eval is deterministic: at most one primitive step applies

\textit{Progress Theorem (restated)}: If \( e \) is well-typed, then there is a decomposition or \( e \) is a value

Continuations

Now that we have defined \( E \) explicitly in our \textit{metalanguage}, what if we also put it on our \textit{language}

- From metalanguage to language is called \textit{reification}

First-class continuations:

\[
e ::= \ldots | \text{letcc } x. e | \text{throw } e | \text{cont } E
\]

\[
v ::= \ldots | \text{cont } E
\]

\[
E ::= \ldots | \text{throw } E | \text{throw } v
\]

\[
E[\text{letcc } x. e] \rightarrow E[(\lambda x. e)(\text{cont } E)] \quad E[\text{throw } (\text{cont } E') v] \rightarrow E'[v]
\]

- New operational rules for \( \rightarrow \) not \( \xrightarrow{P} \) because “the \( E \) matters”
- \text{letcc } x. e grabs the current evaluation context (“the stack”)
- \text{throw } (\text{cont } E') v restores old context: “jump somewhere”
- \text{cont } E not in source programs: “saved stack (value)”

Examples (exceptions-like)

1 + (letcc k. 2 + 3) \( \rightarrow^* \) 6

1 + (letcc k. 2 + (throw k 3)) \( \rightarrow^* \) 4

1 + (letcc k. (throw k (2 + 3))) \( \rightarrow^* \) 6

1 + (letcc k. (throw k (throw k (throw k 2)))) \( \rightarrow^* \) 3

Evaluation Contexts: So what?

Small-step semantics (old) and evaluation-context semantics (new) are very similar:

- Totally equivalent step sequence
  - (made both left-to-right call-by-value)
- Just rearranged things to be more concise: Each boring rule became a form of \( E \)
- Both “work” the same way:
  - Find the next place in the program to take a “primitive step”
  - Take that step
  - Plug the result into the rest of the program
  - Repeat (next “primitive step” could be somewhere else) until you can’t anymore (value or stuck)

Evaluation contexts so far just cleanly separate the “find and plug” from the “take that step” by building an explicit \( E \)
Another view
If you’re confused, think call stacks:
  ▶ What if your favorite language had operations for:
    ▶ Store current stack in x
    ▶ Replace current stack with stack in x
  ▶ “Resume the stack’s hole” with something different or when mutable state is different
    ▶ Else you are sure to have an infinite loop since you will later resume the stack again

Example (“time travel”)
Caml doesn’t have first-class continuations, but if it did:
let valOf x = match x with None-> failwith "" |Some x-> x
let g = ref None
let y = ref (1 + 2 + (letcc k. (g := Some k); 3))
let z = throw (valOf (!g)) 7

Example (“time travel”)
Caml doesn’t have first-class continuations, but if it did:
let val0f x = match x with None-> failwith "" |Some x-> x
let g = ref None
let y = ref (1 + 2 + (letcc k. (g := Some k); 3))
let z = throw (val0f (!g)) 7
Example ("time travel")

Caml doesn’t have first-class continuations, but if it did:

```ocaml
let valOf x = match x with None -> failwith "" | Some x -> x

let g = ref None
let y = ref (1 + 2 + (letcc k. (g := Some k); 3))

let x = ref true (* avoids infinite loop *)
let z = if !x then
  (x := false; throw (valOf (!g)) 7)
else
  !y
```

SML/NJ does: This runs and binds 10 to z:

```ocaml
open SMLofNJ.Cont
val g : int cont option ref = ref NONE
val y = ref (1 + 2 + (callcc (fn k => ((g := SOME k); 3))))
val x = ref true (* avoids infinite loop *)
val z = if !x then (x := false; throw (valOf (!g)) 7) else !y
```

Is this useful?

First-class continuations are a \textit{single} construct sufficient for:

- Exceptions
- Cooperative threads (including coroutines)
  - “yield” captures the continuation (the “how to resume me”) and gives it to the scheduler (implemented in the language), which then throws to another thread’s “how to resume me”
- Other crazy things
  - Often called the “goto of functional programming” — incredibly powerful, but nonstandard uses are usually inscrutable
  - Key point is that we can “jump back in” unlike boring-old exceptions

Where are we

Done:

- Redefined our operational semantics using evaluation contexts
- That made it easy to define first-class continuations
- Example uses of continuations

Now: How the heck do we implement this?

Rather than adding a powerful primitive, we can achieve the same effect via a \textit{whole-program translation} into a sublanguage (source-to-source transformation)

- Every function takes extra arg: \textit{continuation} says what’s next
- Never “return” — instead call current continuation w/ result
- \textit{Every expression becomes a continuation-accepting function}
- Will be able to reintroduce \texttt{letcc} and \texttt{throw} “for free”
CPS examples

Invariant: every function takes continuation as extra argument

let mult' x y k = ...

let mult' x y k = k (x * y)
CPS examples

Invariant: every function takes continuation as extra argument

let mult’ x y k = k (x * y)
let add’ x y k = k (x + y)
let sub’ x y k = k (x - y)
let eq’ x y k = k (x = y)

let rec fact’ n k = ...

OK, now you convert:

let fact n =
aux n 1
let rec aux n acc =
if n = 0 then
acc
else
aux (n - 1) (n * acc)
The CPS transformation (one way to do it)

A metafunction from expressions to expressions

Example source language (other features similar):

\[
e \ ::= \ x \mid \lambda x. \ e \mid e \ e \mid c \mid e + e
\]
\[
v \ ::= \ x \mid \lambda x. \ e \mid c
\]
\[
\text{CPS}_E(v) = \lambda k. \text{CPS}_V(v)
\]
\[
\text{CPS}_E(e_1 + e_2) = \lambda k. \text{CPS}_E(e_1) \lambda x_1. \text{CPS}_E(e_2) \lambda x_2. k (x_1 + x_2)
\]
\[
\text{CPS}_E(e_1 \ e_2) = \lambda k. \text{CPS}_E(e_1) \lambda f. \text{CPS}_E(e_2) \lambda x. f \ x \ k
\]
\[
\text{CPS}_V(c) = c
\]
\[
\text{CPS}_V(x) = x
\]
\[
\text{CPS}_V(\lambda x. \ e) = \lambda x. \lambda k. \text{CPS}_E(e) \ k
\]

To run the whole program \(e\), do \(\text{CPS}_E(e) (\lambda x. \ x)\)

Encoding first-class continuations

If you apply the CPS transform, then you can add letcc and throw “for free” right in the source language

\[
\text{CPS}_E(\text{letcc \ } k. \ e) = \lambda k. \text{CPS}_E(e) \ k
\]
\[
\text{CPS}_E(\text{throw \ } e_1 \ e_2) = \lambda k. \text{CPS}_E(e_1) \lambda x_1. \text{CPS}_E(e_2) \left( \lambda x_2. x_1 \ x_2 \right)
\]

- **letcc** gets passed the current continuation just as it needs
- **throw** ignores the current continuation just as it should

You can also manually program in this style (fully or partially)

- Has other uses as a programming idiom too...

A useful advanced programming idiom

- A first-class continuation can “reify session state” in a client-server interaction
  - If the continuation is passed to the client, which returns it later, then the server can be stateless
  - Suggests CPS for web programming
  - Better: tools that do the CPS transformation for you
    - Gives you a “prompt-client” primitive without server-side state

- Because CPS uses only tail calls, it avoids deep call stacks when traversing recursive data structures
  - See lec13code.ml for this and related idioms

In short, “thinking in terms of CPS” is a powerful technique few programmers have...
