Announcements:

- Submit your project group **TODAY** if you haven't (Ed Pinned Post)
- Project Proposal due this Thursday (no late periods)
 Submit on Gradescope as a group once
- Upload homework on time (23:59pm)
- We'd love to hear your feedback through our form
 - We spend hours every week reviewing feedback and improving this course!

Recommender Systems: Content-based Systems & Collaborative Filtering

CSE547 Machine Learning for Big Data Tim Althoff PAUL G. ALLEN SCHOOL OF COMPUTER SCIENCE & ENGINEERING

High Dimensional Data

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Example: Recommender Systems

Customer X

- Buys Metallica CD
- Buys Megadeth CD

Customer Y

- Does search on Metallica
- Recommender system suggests Megadeth from data collected about customer X

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Recommendations

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

From Scarcity to Abundance

- Shelf space is a scarce commodity for traditional retailers
 - Also: TV networks, movie theaters,...
- Web enables near-zero-cost dissemination of information about products
 - From scarcity to abundance
- More choice necessitates better filters:
 - Recommendation engines
 - Association rules: How Into Thin Air made Touching the Void a bestseller: <u>A WIRED article about the story</u>

Sidenote: The Long Tail

1/23/23

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Physical vs. Online

THE BIT PLAYER Advantage

Beyond bricks and mortar there are two main retail models – one that gets halfway down the Long Tail and another that goes all the way. The first is the familiar hybrid model of Amazon and Netflix, companies that sell physical goods online. Digital catalogs allow them to offer unlimited selection along with search, reviews, and recommendations, while the cost savings of massive warehouses and no walk-in customers greatly expands the number of products they can sell profitably.

Pushing this even further are pure digital services, such as iTunes, which offer the additional savings of delivering their digital goods online at virtually no marginal cost. Since an extra database entry and a few megabytes of storage on a server cost effectively nothing, these retailers have no economic reason not to carry *everything* available.

States and states

Read <u>A WIRED article about the story of the Association Rules books</u> to learn more!

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Types of Recommendations

Editorial and hand curated

- List of favorites
- Lists of "essential" items

Simple aggregates

Top 10, Most Popular, Recent Uploads

Tailored to individual users

Amazon, Netflix, ...

Formal Model

- X = set of Customers
- S = set of Items
- Utility function $u: X \times S \rightarrow R$
 - **R** = set of ratings
 - **R** is a totally ordered set
 - e.g., **1-5** stars, real number in **[0,1]**

Utility Matrix

Key Problems

• (1) Gathering "known" ratings for matrix

- How to collect the data in the utility matrix
- (2) Extrapolating unknown ratings from the known ones
 - Mainly interested in high unknown ratings
 - We are not interested in knowing what you don't like but what you like

(3) Evaluating extrapolation methods

 How to measure success/performance of recommendation methods

(1) Gathering Ratings

Explicit

- Ask people to rate items
- Doesn't work well in practice people don't like being bothered
- Crowdsourcing: Pay people to label items

Implicit

- Learn ratings from user actions
 - E.g., purchase implies high rating
 - E.g., add to playlist, play in full, skip song...
- What about low ratings?

(2) Extrapolating Utilities

- Key problem: Utility matrix U is sparse
 - Most people have not rated most items
 - Cold Start Problem:
 - New items have no ratings
 - New users have no history

Three approaches to recommender systems:

- 1) Content-based
 2) Collaborative
- 3) Latent factor based

Content-based Recommender Systems

Content-based Recommendations

Main idea: Recommend items to customer x similar to previous items rated highly by x

Example:

Movie recommendations

 Recommend movies with same actor(s), director, genre, ...

Websites, blogs, news

Recommend other sites with "similar" content

Plan of Action

Item Profiles

- For each item, create an item profile
- Profile is a set (vector) of features
 - Movies: author, title, actor, director,...
 - **Text:** Set of "important" words in document
- How to pick important features?
 - Usual heuristic from text mining is TF-IDF (Term frequency * Inverse Doc Frequency)
 - Term ... Feature
 - Document ... Item

Sidenote: TF-IDF

 f_{ij} = frequency of term (feature) i in doc (item) j

 $TF_{ij} = \frac{f_{ij}}{\max_k f_{kj}} \quad \diamondsuit$ Large when term *i* appears often in doc *j*

Note: we normalize TF to discount for "longer" documents

n_i = number of docs that mention term *i N* = total number of docs

 $IDF_i = \log \frac{N}{n_i} \quad \diamondsuit$ Large when term *i* appears in very few documents

TF-IDF score: $w_{ij} = TF_{ij} \times IDF_i$

Doc profile = set of words with highest **TF-IDF** scores, together with their scores

User Profiles and Prediction

User profile possibilities:

- Weighted average of rated item profiles
- Variation: weight by difference from average rating for item
- Prediction heuristic: Cosine similarity of user and item profiles)

• Given user profile **x** and item profile **i**, estimate $u(\mathbf{x}, \mathbf{i}) = \cos(\mathbf{x}, \mathbf{i}) = \frac{x \cdot \mathbf{i}}{||\mathbf{x}|| \cdot ||\mathbf{i}||}$

How do you quickly find items closest to x?
Job for LSH!

Pros: Content-based Approach

- +: No need for data on other users
 - No cold-start or sparsity problems
- +: Able to recommend to users with unique tastes
- +: Able to recommend new & unpopular items
 - No first-rater problem
- +: Able to provide explanations
 - Can provide explanations of recommended items by listing content-features that caused an item to be recommended

Cons: Content-based Approach

- -: Finding the appropriate features is hard
 - E.g., images, movies, music
- -: Recommendations for new users
 - How to build a user profile?
- -: Overspecialization
 - Never recommends items outside user's content profile
 - People might have multiple interests
 - I Unable to exploit quality judgments of other users!

Collaborative Filtering

Harnessing quality judgments of other users

Collaborative Filtering

- Consider user **x**
- Find set N of other users whose ratings are "similar" to x's ratings
- Estimate x's ratings based on ratings of users in N

Finding "Similar" Users $r_x = [*, _, _, *, **]$ $r_y = [*, _, *, **, **]$

Let r_x be the vector of user x's ratings

Jaccard similarity metric

Problem: Ignores the value of the rating
 Cosine similarity metric

$$sim(x, y) = cos(r_x, r_y) = \frac{r_x \cdot r_y}{||r_x|| \cdot ||r_y||} \qquad r_x, r_y \text{ as points:} \\ r_x = \{1, 0, 0, 1, 3\} \\ r_y = \{1, 0, 2, 2, 0\}$$

r_x, *r_y* as sets: *r_x* = {1, 4, 5}

 $r_v = \{1, 3, 4\}$

Problem: Treats some missing ratings as "negative"

Better: Pearson correlation coefficient

•
$$S_{xy}$$
 = items rated by both users x and y
 $sim(x, y) = \frac{\sum_{s \in S_{xy}} (r_{xs} - \overline{r_x}) (r_{ys} - \overline{r_y})}{\sqrt{\sum_{s \in S_{xy}} (r_{xs} - \overline{r_x})^2} \sqrt{\sum_{s \in S_{xy}} (r_{ys} - \overline{r_y})^2}} \overline{r_x, \overline{r_y} \dots avg}$

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Similarity Metric

- Intuitively we want: sim(A, B) > sim(A, C)
- Jaccard similarity: 1/5 < 2/4
- Cosine similarity: 0.380 > 0.322
 - Considers missing ratings as "negative"
 - Solution: subtract the (row) mean

	HP1	HP2	HP3	TW	SW1	SW2	SW3
A	2/3	otherse		5/3	-7/3		
B	1/3	1/3	-2/3				
C				-5/3	1/3	4/3	
D		0					0

sim A, B vs. A, C: 0.092 > -0.559

sine sim: $sim(x,y) = \frac{\sum_{i} r_{xi} \cdot r_{yi}}{\sqrt{\sum_{i} r_{xi}^2} \cdot \sqrt{\sum_{i} r_{yi}^2}}$

Cosine sim:

Notice cosine sim, is correlation when data is centered at 0

Page 26

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Rating Predictions

From similarity metric to recommendations:

- Let r_x be the vector of user x's ratings
- Let N be the set of k users most similar to x who have rated item i
- Prediction for item i of user x:

•
$$r_{xi} = \frac{1}{k} \sum_{y \in N} r_{yi}$$

• Or even better:
$$r_{xi} = \frac{\sum_{y \in N} s_{xy} \cdot r_{yi}}{\sum_{y \in N} s_{xy}}$$

Shorthand: $s_{xy} = sim(x, y)$

Many other tricks possible...

Item-Item Collaborative Filtering

- So far: User-user collaborative filtering
- Another view: Item-item
 - For item *i*, find other similar items
 - Estimate rating for item *i* based on ratings for similar items
 - Can use same similarity metrics and prediction functions as in user-user model

 $\frac{J \in N(i;x) S_{ij}}{\sum} S_{ij}$ xi

s_{ij}... similarity of items *i* and *j*r_{xj}...rating of user *x* on item *j*N(*i*;*x*)... set items which were rated by *x* and similar to *i*

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

users

1/23/23

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

?

users

- estimate rating of movie 1 by user 5

1/23/23

movies

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Neighbor selection: Identify movies similar to movie 1, rated by user 5 Here we use Pearson correlation as similarity: 1) Subtract mean rating m_i from each movie i $m_1 = (1+3+5+5+4)/5 = 3.6$ *row 1:* [-2.6, 0, -0.6, 0, 0, 1.4, 0, 0, 1.4, 0, 0.4, 0]

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

1/23/23

Page 31

Compute similarity weights:

s_{1,3}=0.41, s_{1,6}=0.59

1/23/23

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

 $r_{1.5} = (0.41^{*}2 + 0.59^{*}3) / (0.41 + 0.59) = 2.6$

CF: Common Practice

- Define similarity s_{ij} of items i and j
- Select k nearest neighbors N(i; x)
 - Items most similar to *i*, that were rated by *x*
- Estimate rating r_{xi} as the weighted average:

baseline estimate for r_{xi} $b_{xi} = \mu + b_x + b_i$ $b_x = rating deviation of user x$ $= (avg. rating of user x) - \mu$ $b_i = rating deviation of movie i$

Item-Item vs. User-User

- In practice, it has been observed that <u>item-item</u> often works better than user-user
- Why? Items are simpler, users have multiple tastes

Pros/Cons of Collaborative Filtering

+ Works for any kind of item

No feature selection needed

- Cold Start:

Need enough users in the system to find a match

- Sparsity:

- The user/ratings matrix is sparse
- Hard to find users that have rated the same items

- First rater:

- Cannot recommend an item that has not been previously rated
- New items, Esoteric items
- Popularity bias:
 - Cannot recommend items to someone with unique taste
 - Tends to recommend popular items

Hybrid Methods

- Implement two or more different recommenders and combine predictions
 - Perhaps using a linear model
- Add content-based methods to collaborative filtering
 - Item profiles for new item problem
 - Demographics to deal with new user problem

Remarks & Practical Tips

- Evaluation
- Error metrics
- Complexity / Speed

Evaluation

Evaluation

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547

Evaluating Predictions

Compare predictions with known ratings

- Root-mean-square error (RMSE)
 - $\sqrt{\frac{1}{N}\sum_{xi}(r_{xi} r_{xi}^*)^2}$ where r_{xi} is predicted, r_{xi}^* is the true rating of x on iN is the number of points we are making comparisons on
- Rank Correlation:
 - Spearman's correlation between system's and user's complete rankings
- Precision at top 10 (or k):
 % of those in top 10 (or k)

Another approach: 0/1 model

- **Coverage:**
 - Number of items/users for which the system can make predictions
- Precision:
 - Accuracy of predictions
- Receiver operating characteristic (ROC)
 - Tradeoff curve between false positives and false negatives

Problems with Error Metrics

- Narrow focus on accuracy sometimes misses the point
 - Prediction Diversity
 - Prediction Context
 - Order of predictions
- In practice, we care only to predict high ratings:
 - RMSE might penalize a method that does well for high ratings and badly for others

Collaborative Filtering: Complexity

- Expensive step is finding k most similar customers: O(|X|)
- Too expensive to do at runtime
 - Could pre-compute
- Pre-computation takes time O(k · |X|)

X ... set of customers

We already know how to do this!

- Near-neighbor search in high dimensions (LSH)
- Clustering
- Dimensionality reduction

Tip: Add Data

Leverage all the data

- Don't try to reduce data size in an effort to make fancy algorithms work
- Simple methods on large data do best

Add more data

e.g., add IMDB data on genres

More data beats better algorithms

A blog post about more data is important

On Thursday: The Netflix prize and the Latent Factor Models

On Thursday: The Netflix Prize

Training data

- 100 million ratings, 480,000 users, 17,770 movies
 - Lots of ratings still 99% sparsity!
- 6 years of data: 2000-2005

Test data (private)

- Last few ratings of each user (2.8 million)
- Evaluation criterion: root mean squared error (RMSE)
- Netflix Cinematch RMSE (production): 0.9514

Competition

- 2700+ teams
- \$1 million prize for 10% improvement on Cinematch

On Thursday: Latent Factor Models

Next topic: Recommendations via Latent Factor models

Popular Roasts and Blends

Overview of Coffee Varieties

Complexity of Flavor

The bubbles above represent products sized by sales volume. Products close to each other are recommended to each other.

[slide from winning Bellkor Team]

Latent Factor Models (i.e., SVD++)

Tim Althoff, UW CS547: Machine Learning for Big Data, http://www.cs.washington.edu/cse547
