# CSE 573: Artificial Intelligence

Hanna Hajishirzi

Search

(Un-informed, Informed Search)

### Recap: Search

#### Search problem:

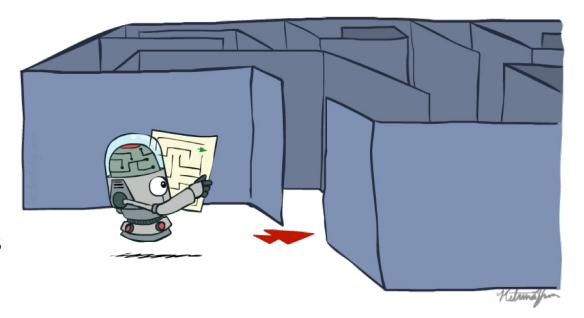

- States (configurations of the world)
- o Actions and costs
- Successor function (world dynamics)
- o Start state and goal test

#### Search tree:

o Nodes: represent plans for reaching states

#### Search algorithm:

- Systematically builds a search tree
- Chooses an ordering of the fringe (unexplored nodes)
- o Optimal: finds least-cost plans

#### General Tree Search

```
function TREE-SEARCH( problem, strategy) returns a solution, or failure initialize the search tree using the initial state of problem loop do

if there are no candidates for expansion then return failure choose a leaf node for expansion according to strategy

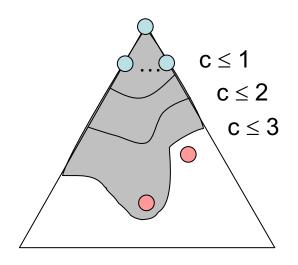

if the node contains a goal state then return the corresponding solution else expand the node and add the resulting nodes to the search tree end
```

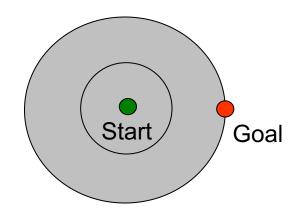

#### **Uniform Cost Issues**

 Remember: UCS explores increasing cost contours

The good: UCS is complete and optimal!

- o The bad:
  - Explores options in every "direction"
  - No information about goal location

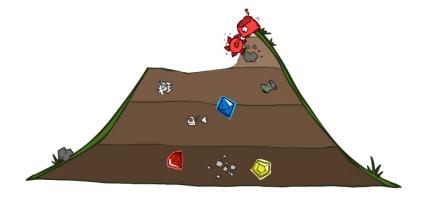

• We'll fix that soon!

### Up next: Informed Search

- Uninformed Search
  - o DFS
  - o BFS
  - o UCS

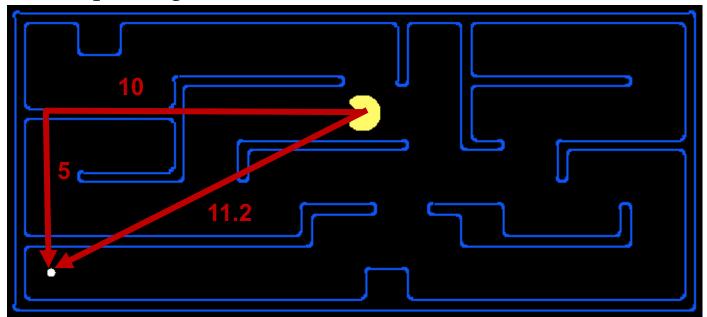

- Informed Search
  - Heuristics
  - Greedy Search
  - A\* Search
  - Graph Search

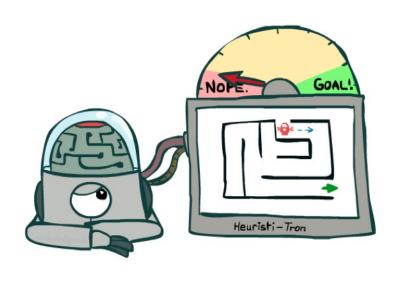

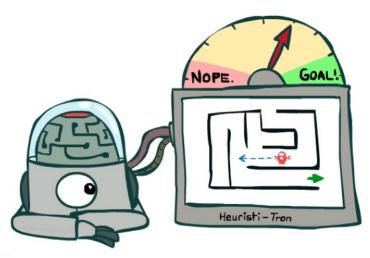

### Search Heuristics

#### A heuristic is:

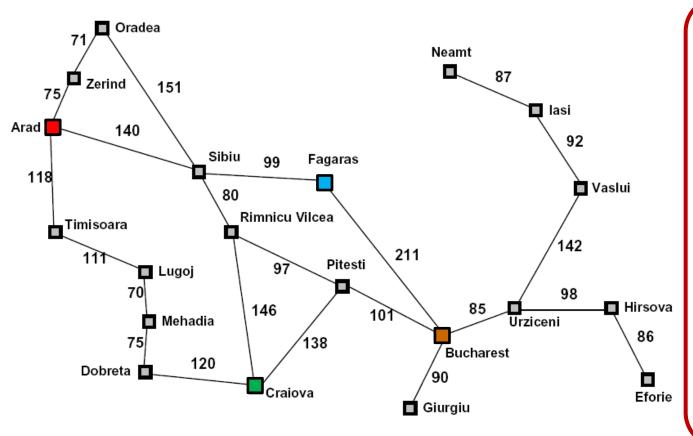

- A function that *estimates* how close a state is to a goal
- Designed for a particular search problem
- Pathing?
- Examples: Manhattan distance, Euclidean distance for pathing

### Example: Heuristic Function

Straight-line distanto Bucharest	ice
	266
Arad	366
Bucharest	0
Craiova	160
Dobreta	242
Eforie	161
Fagaras	178
Giurgiu	77
Hirsova	151
Iasi	226
Lugoj	244
Mehadia	241
Neamt	234
Oradea	380
Pitesti	98
Rimnicu Vilcea	193
Sibiu	253
Timisoara	329
Urziceni	80
Vaslui	199
Zerind	374

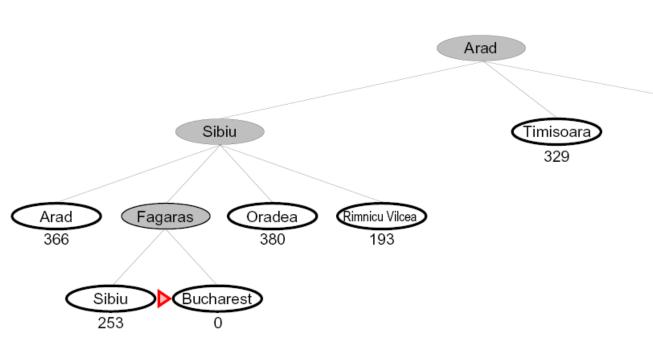

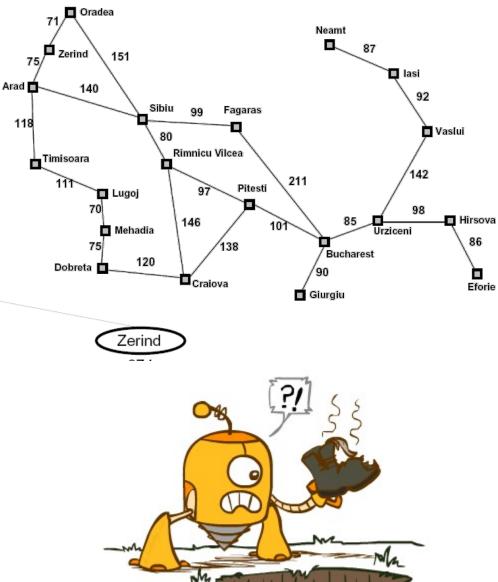

# Greedy Search

## Greedy Search

o Expand the node that seems closest...

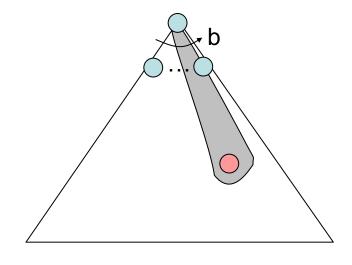

- o Is it optimal?
  - o No. Resulting path to Bucharest is not the shortest!

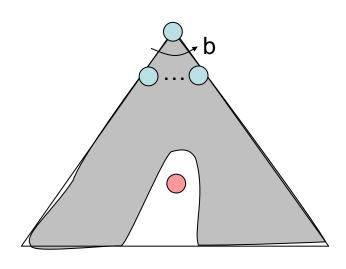

### Greedy Search

- Strategy: expand a node that you think is closest to a goal state
  - Heuristic: estimate of distance to nearest goal for each state

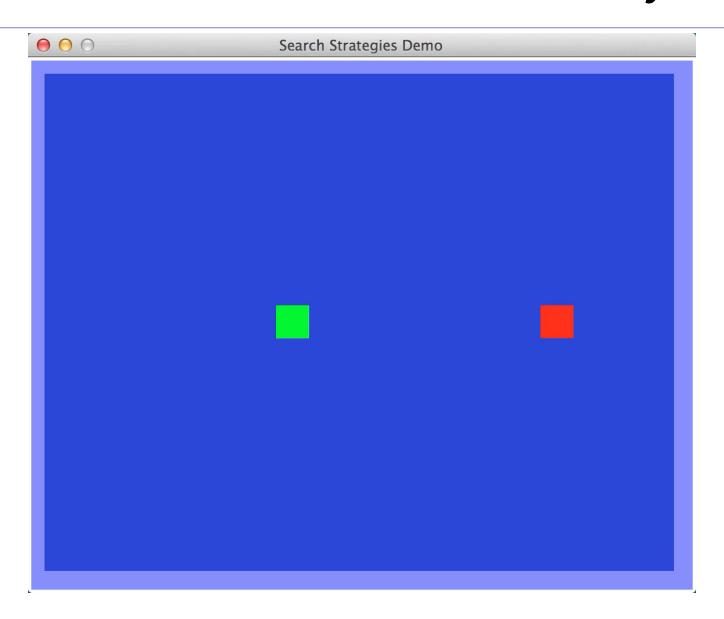

- A common case:
  - o Best-first takes you straight to the (wrong) goal

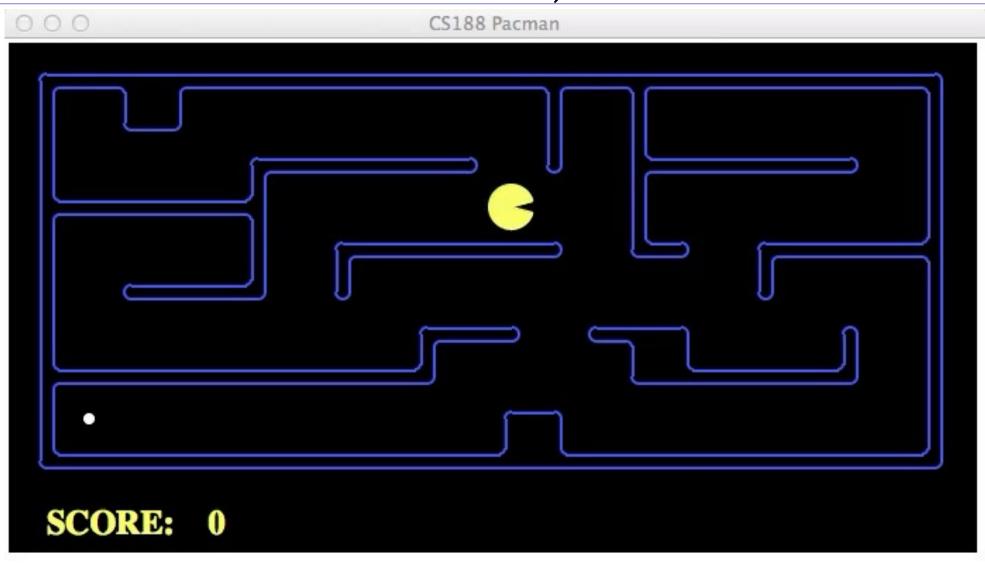

Worst-case: like a badly-guided DFS

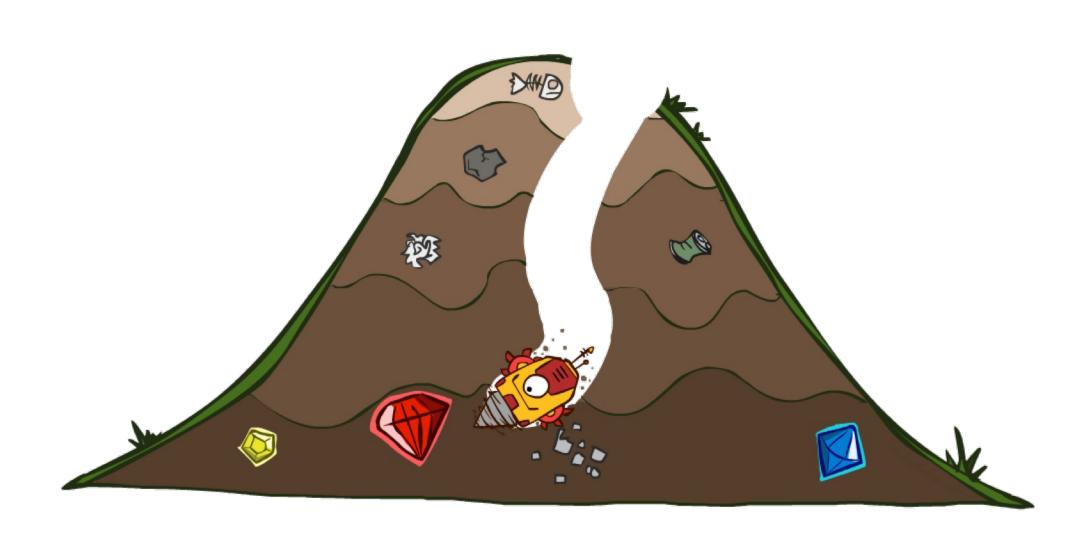

### Video of Demo Contours Greedy (Empty)

# Video of Demo Contours Greedy (Pacman Small Maze)

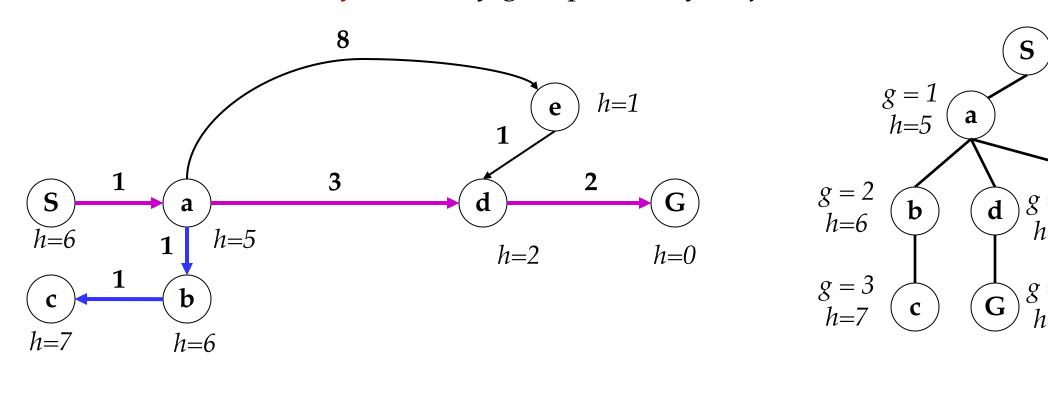

### A\* Search

### A\* Search

### Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost g(n)
- Greedy orders by goal proximity, or forward cost h(n)

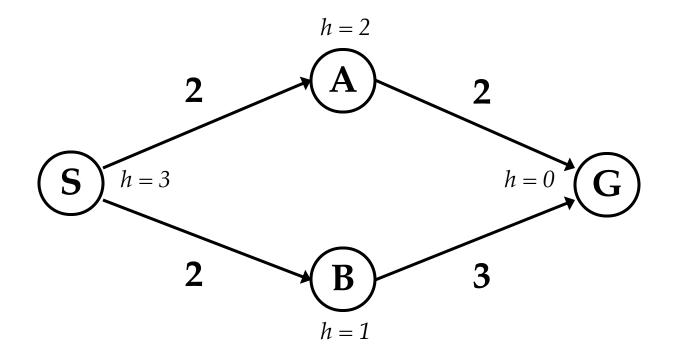

o A\* Search orders by the sum: f(n) = g(n) + h(n)

Example: Teg Grenager

h=6

### When should A\* terminate?

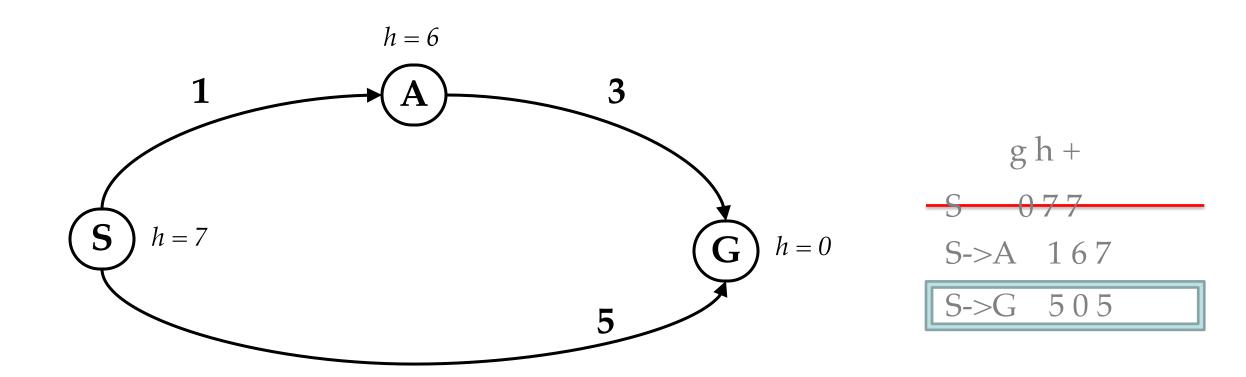

o Should we stop when we enqueue a goal?

No: only stop when we dequeue a goal

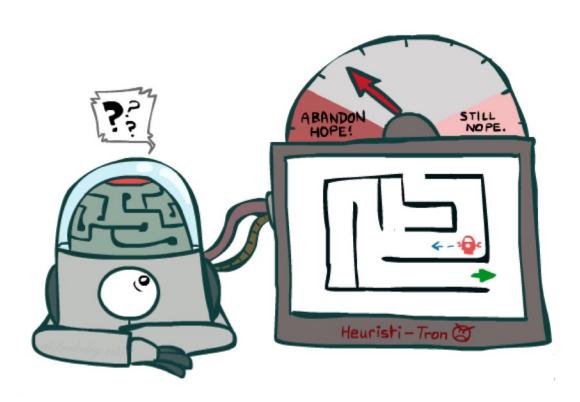

S->A->G 4 0 4

### Is A\* Optimal?

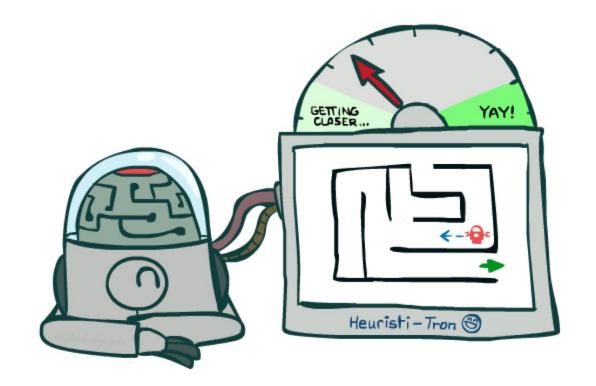

- What went wrong?
- Actual bad goal cost < estimated good goal cost</li>
- We need estimates to be less than actual costs!

### Idea: Admissibility

Inadmissible (pessimistic) heuristics break optimality by trapping good plans on the fringe

Admissible (optimistic) heuristics slow down bad plans but never outweigh true costs

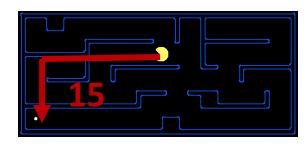

### Admissible Heuristics

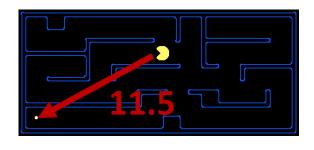

• A heuristic *h* is *admissible* (optimistic) if:

$$0 \le h(n) \le h^*(n)$$

where  $h^*(n)$  is the true cost to a nearest goal

o Examples:

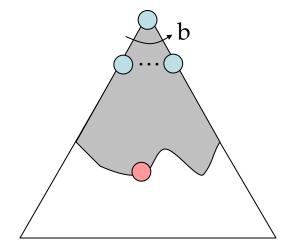

0.0

 Coming up with admissible heuristics is most of what's involved in using A\* in practice.

## Properties of A\*

**Uniform-Cost** 

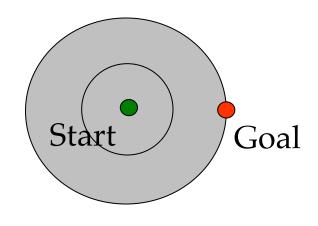

**A**\*

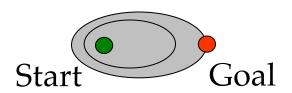

#### UCS vs A\* Contours

 Uniform-cost expands equally in all "directions"

 A\* expands mainly toward the goal, but does hedge its bets to ensure optimality

### Comparison

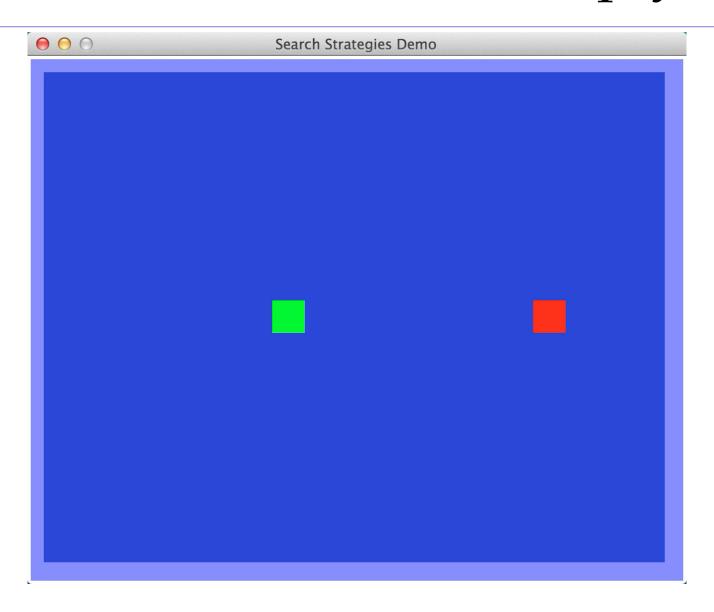

Greedy

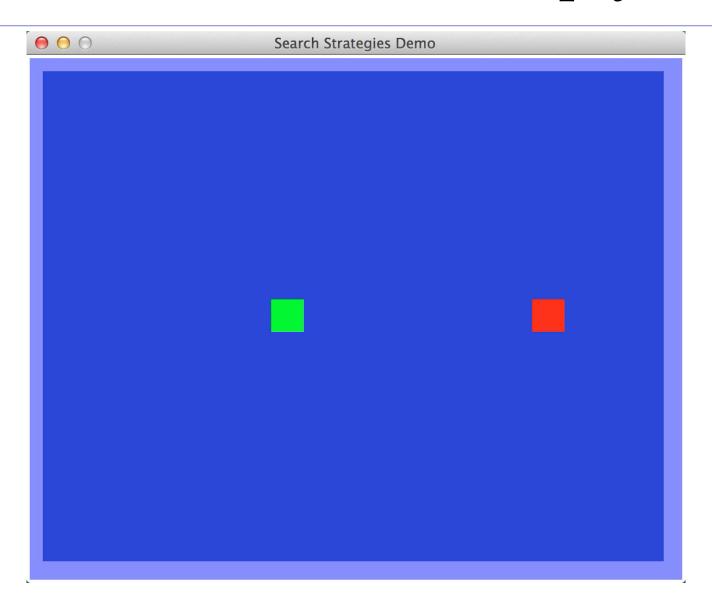

**Uniform Cost** 

**A**\*

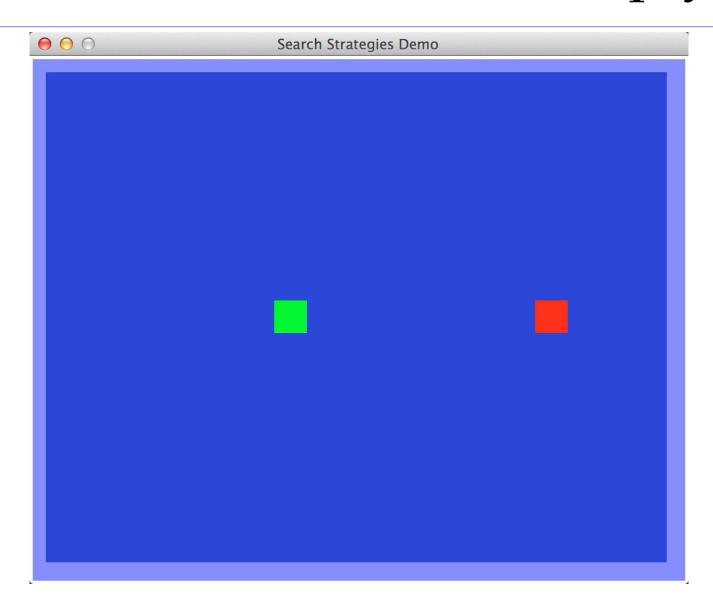

### Video of Demo Contours (Empty) -- UCS

### Video of Demo Contours (Empty) -- Greedy

### Video of Demo Contours (Empty) – A\*

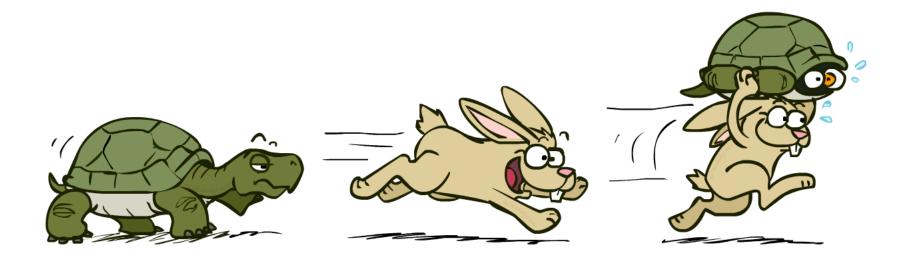

# A\*: Summary

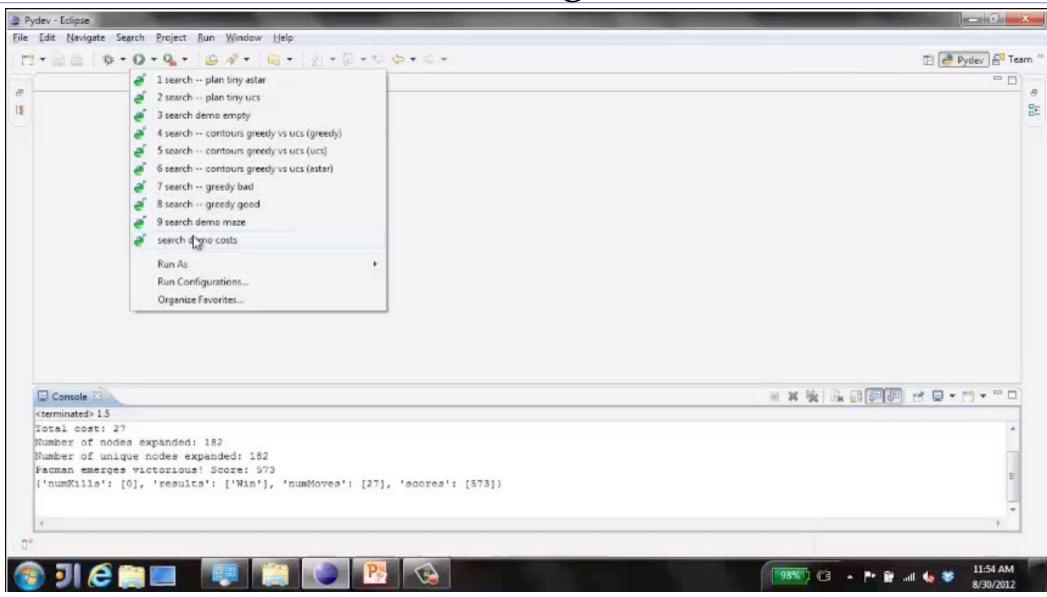

### A\*: Summary

- A\* uses both backward costs and (estimates of) forward costs
- A\* is optimal with admissible (optimistic) heuristics
- Heuristic design is key: often use relaxed problems

# Video of Demo Empty Water Shallow / Deep – Guess Algorithm

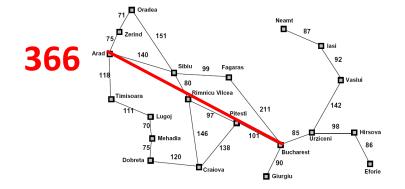

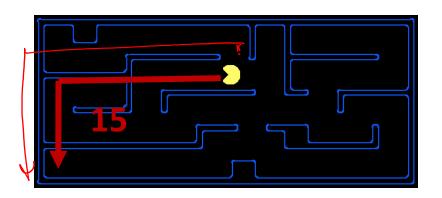

### Creating Heuristics

### Creating Admissible Heuristics

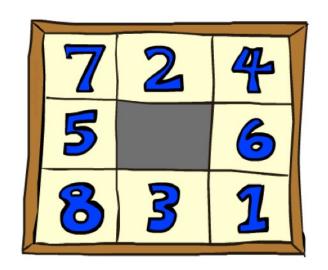

- Most of the work in solving hard search problems optimally is in coming up with admissible heuristics
- Often, admissible heuristics are solutions to relaxed problems, where new actions are available

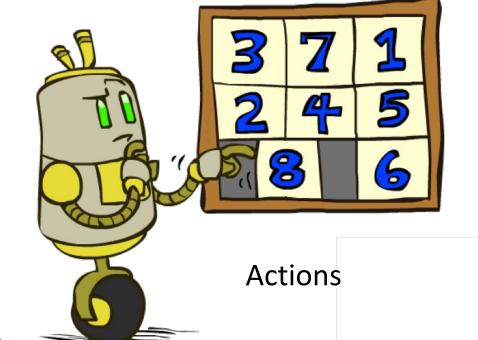

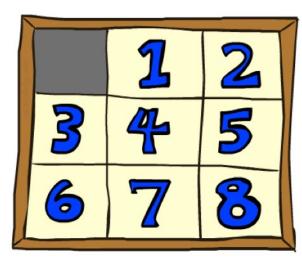

Inadmissible heuristics are often useful too

### Example: 8 Puzzle

**Start State** 

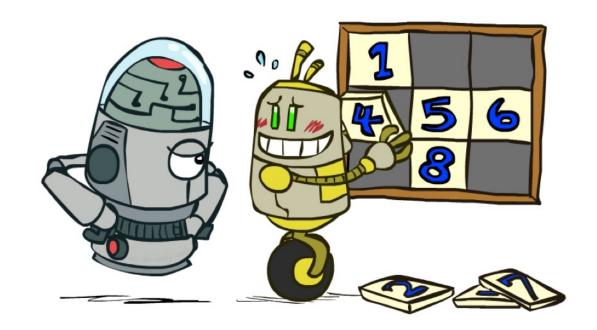

**Goal State** 

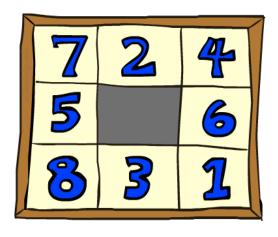

- O What are the states?
- o How many states?
- What are the actions?
- o How many successors from the start state?
- O What should the costs be?

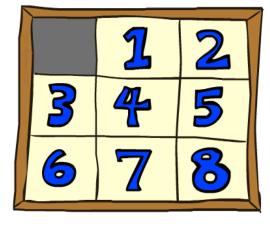

Admissible heuristics?

### 8 Puzzle I

- Heuristic: Number of tiles misplaced
- Why is it admissible?
- h(start) =8
- This is a *relaxed-problem* heuristic

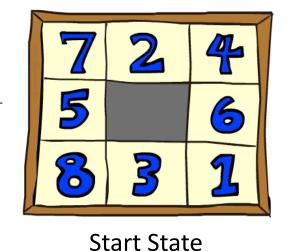

**Start State** 

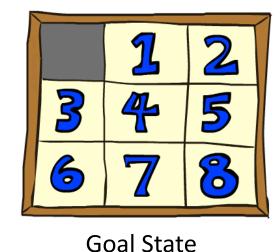

**Goal State** 

	Average nodes expanded when the optimal path has			
	4 steps	8 steps	12 steps	
UCS	112	6,300	3.6 x 10 <sup>6</sup>	
TILES	13	39	227	

#### 8 Puzzle II

 What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?

Total Manhattan distance

Why is it admissible?

oh(start) = 3 + 1 + 2 + ... = 18

	Average nodes expanded when the optimal path has			
	4 steps	8 steps	12 steps	
TILES	13	39	227	
MANHATTAN	12	25	73	

#### 8 Puzzle III

- How about using the actual cost as a heuristic?
  - o Would it be admissible?
  - o Would we save on nodes expanded?
  - o What's wrong with it?

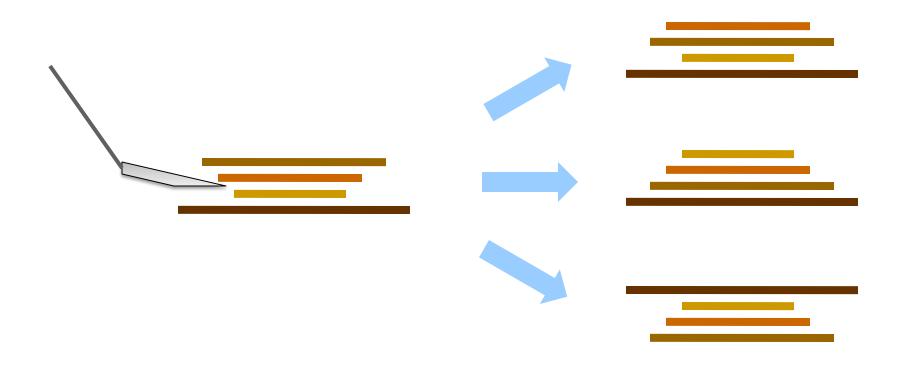

- With A\*: a trade-off between quality of estimate and work per node
  - o As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself

### Example: Pancake Problem

Cost: Number of pancakes flipped

### Example: Pancake Problem

#### BOUNDS FOR SORTING BY PREFIX REVERSAL

William H. GATES

Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU\*†

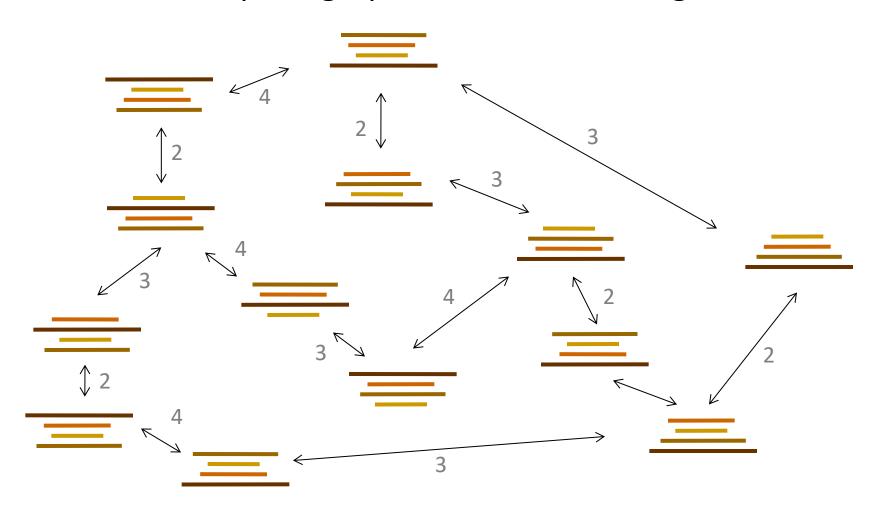

Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

For a permutation  $\sigma$  of the integers from 1 to n, let  $f(\sigma)$  be the smallest number of prefix reversals that will transform  $\sigma$  to the identity permutation, and let f(n) be the largest such  $f(\sigma)$  for all  $\sigma$  in (the symmetric group)  $S_n$ . We show that  $f(n) \leq (5n+5)/3$ , and that  $f(n) \geq 17n/16$  for n a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey  $3n/2 - 1 \leq g(n) \leq 2n + 3$ .

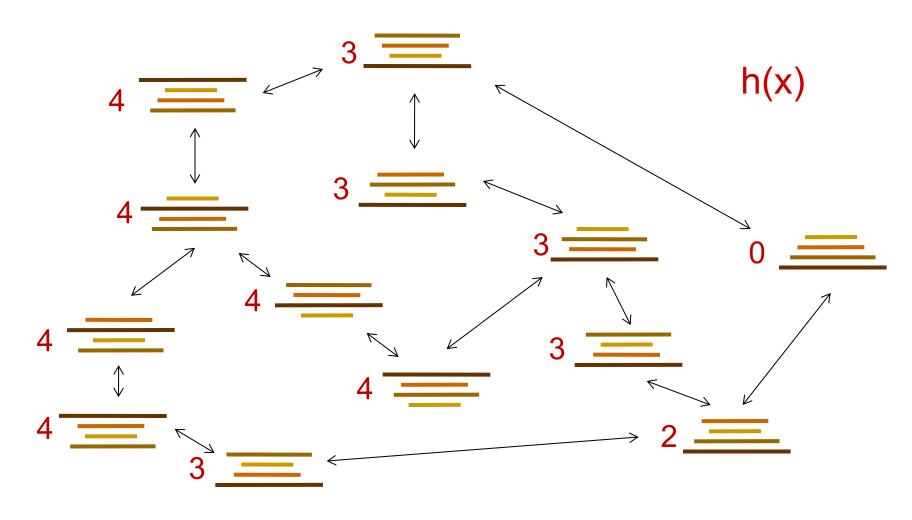

## Example: Pancake Problem

State space graph with costs as weights

## Example: Heuristic Function

Heuristic: the number of the largest pancake that is still out of place

# Semi-Lattice of Heuristics

### Trivial Heuristics, Dominance

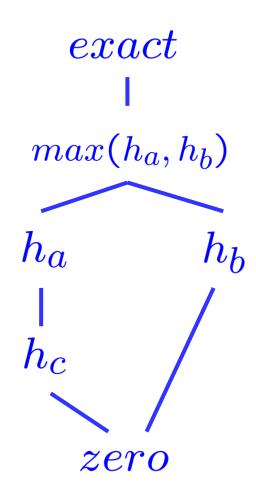

○ Dominance:  $h_a \ge h_c$  if

$$\forall n: h_a(n) \geq h_c(n)$$

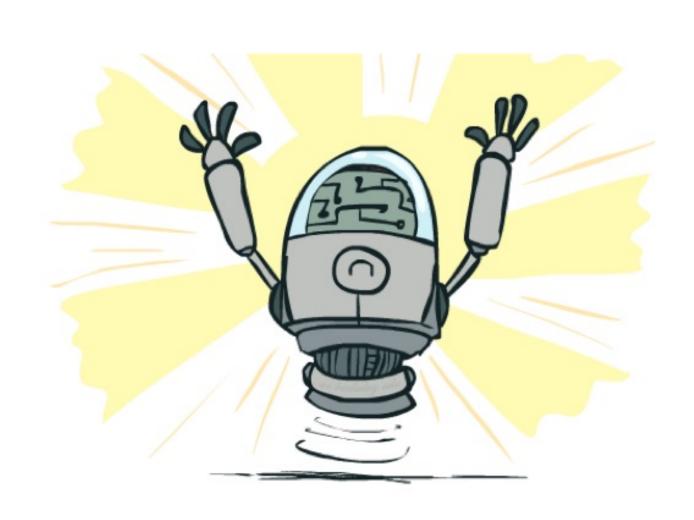

- Heuristics form a semi-lattice:
  - o Max of admissible heuristics is admissible

$$h(n) = max(h_a(n), h_b(n))$$

- Trivial heuristics
  - Bottom of lattice is the zero heuristic (what does this give us?)
  - o Top of lattice is the exact heuristic

# Optimality of A\* Tree Search

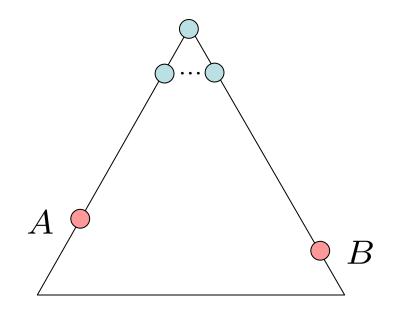

# Optimality of A\* Tree Search

#### Assume:

- A is an optimal goal node
- B is a suboptimal goal node
- o h is admissible

#### Claim:

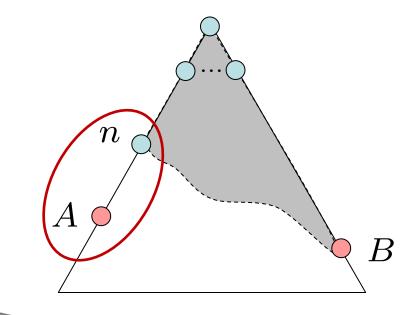

A will exit the fringe before B

# Optimality of A\* Tree Search: Blocking

#### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)

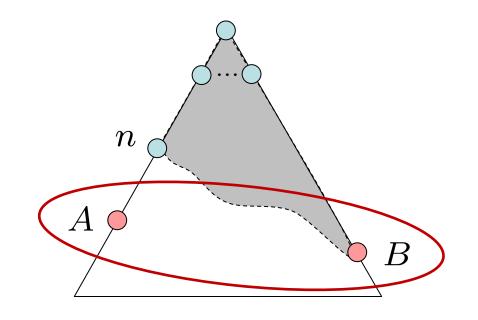

$$f(n) = g(n) + h(n)$$
$$f(n) \le g(A)$$
$$g(A) = f(A)$$

Definition of f-cost Admissibility of h h = 0 at a goal

# Optimality of A\* Tree Search: Blocking

#### Proof:

- Imagine B is on the fringe
- Some ancestor *n* of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B)

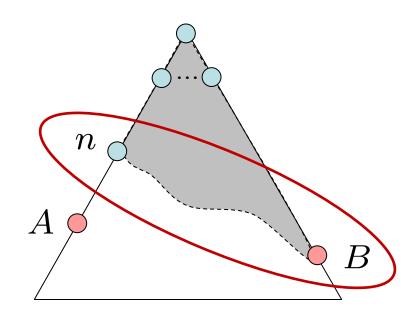

B is suboptimal

$$h = 0$$
 at a goal

# Optimality of A\* Tree Search: Blocking

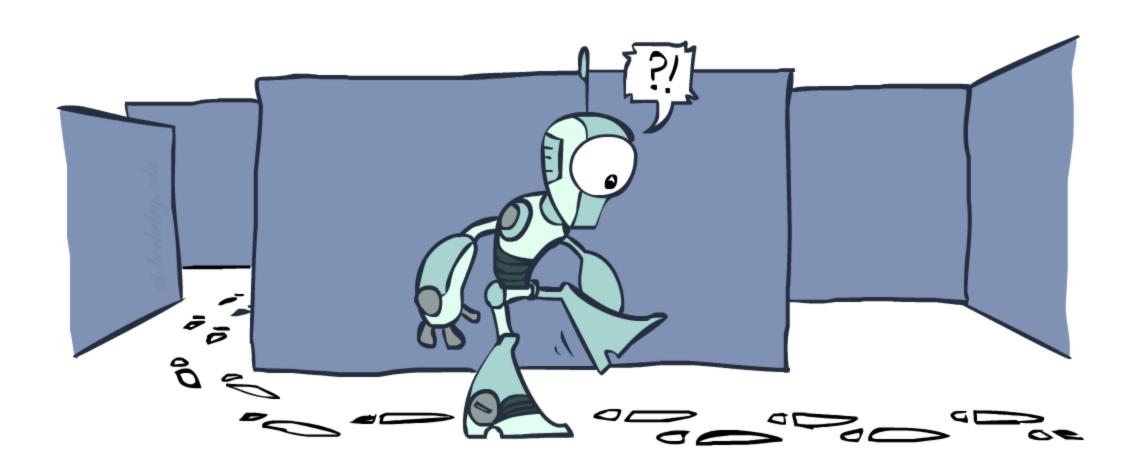

#### Proof:

- Imagine B is on the fringe
- Some ancestor n of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B
  - 1. f(n) is less or equal to f(A)
  - 2. f(A) is less than f(B)
  - 3. *n* expands before B
- All ancestors of A expand before B
- A expands before B
- A\* search is optimal

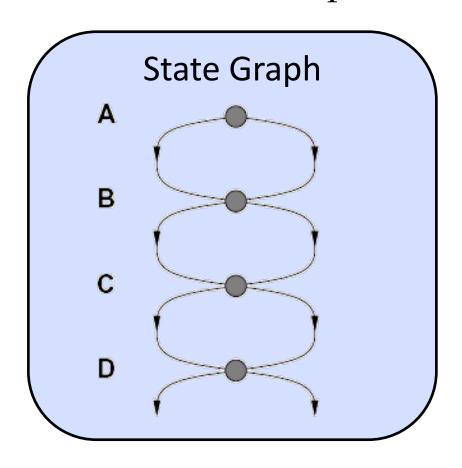

$$\underline{f(n) \le \underline{f(A)} < f(B)}$$

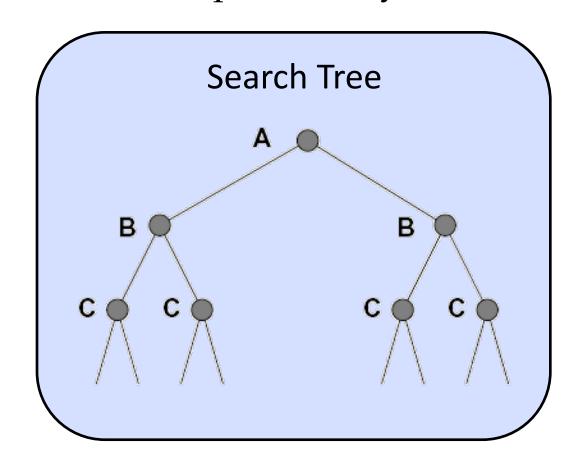

# Graph Search

### Tree Search: Extra Work!

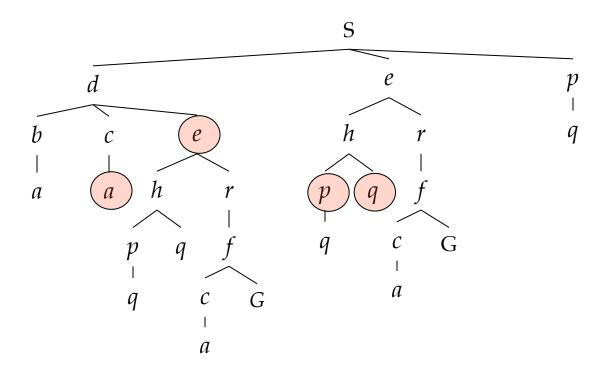

Failure to detect repeated states can cause exponentially more work.

## Graph Search

 In BFS, for example, we shouldn't bother expanding the circled nodes (why?)

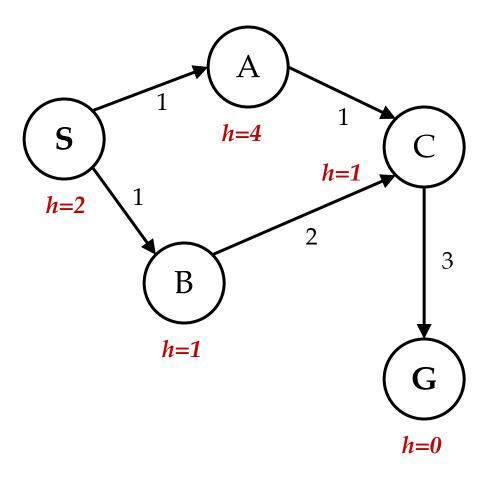

## Graph Search

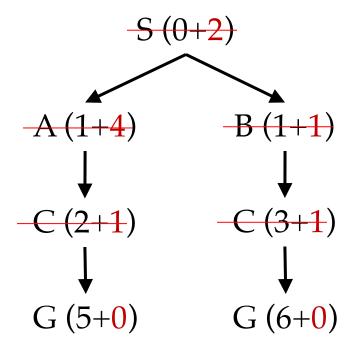

- Idea: never expand a state twice
- How to implement:
  - Tree search + set of expanded states ("closed set")
  - o Expand the search tree node-by-node, but...
  - Before expanding a node, check to make sure its state has never been expanded before
  - o If not new, skip it, if new add to closed set
- Important: store the closed set as a set, not a list
- Can graph search wreck completeness? Why/why not?
- How about optimality?

# A\* Graph Search Gone Wrong?

State space graph

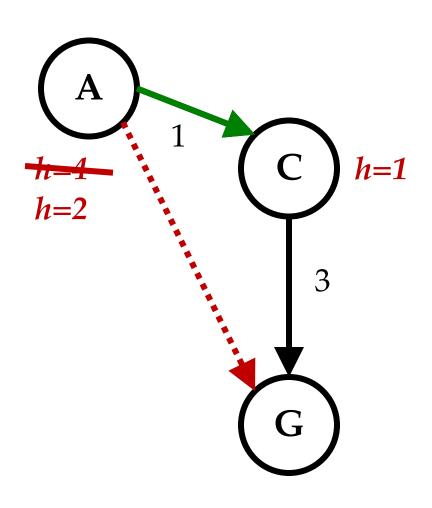

Search tree

Closed Set:S B C A

## Consistency of Heuristics

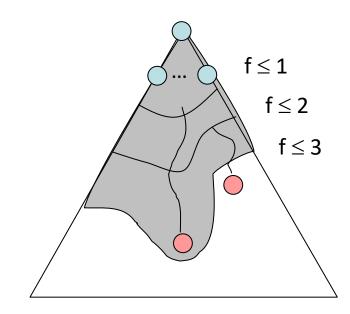

- Main idea: estimated heuristic costs ≤ actual costs
  - Admissibility: heuristic cost ≤ actual cost to goal
     h(A) ≤ actual cost from A to G
  - Consistency: heuristic "arc" cost ≤ actual cost for each
     arc

$$h(A) - h(C) \le cost(A \text{ to } C)$$

- Consequences of consistency:
  - The f value along a path never decreases  $h(A) \le cost(A \text{ to } C) + h(C)$
  - A\* graph search is optimal

### A\* Graph Search

- Sketch: consider what A\* does with a consistent heuristic:
  - Fact 1: In tree search, A\* expands nodes in increasing total f value (f-contours)
  - Fact 2: For every state s, nodes that reach s optimally are expanded before nodes that reach s suboptimally
  - Result: A\* graph search is optimal

## Optimality of A\* Search

- With a admissible heuristic, Tree A\* is optimal.
- With a consistent heuristic, Graph A\* is optimal.
- With h=0, the same proof shows that UCS is optimal.

#### Pseudo-Code

```
function Tree-Search(problem, fringe) return a solution, or failure

fringe \leftarrow Insert(make-node(initial-state[problem]), fringe)

loop do

if fringe is empty then return failure

node \leftarrow remove-front(fringe)

if Goal-test(problem, state[node]) then return node

for child-node in expand(state[node], problem) do

fringe \leftarrow insert(child-node, fringe)

end

end
```

```
function GRAPH-SEARCH(problem, fringe) return a solution, or failure

closed ← an empty set

fringe ← Insert(make-node(initial-state[problem]), fringe)

loop do

if fringe is empty then return failure

node ← REMOVE-FRONT(fringe)

if GOAL-TEST(problem, STATE[node]) then return node

if STATE[node] is not in closed then

add STATE[node] to closed

for child-node in EXPAND(STATE[node], problem) do

fringe ← INSERT(child-node, fringe)

end

end
```

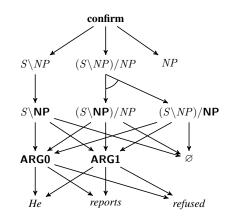

## A\* Applications

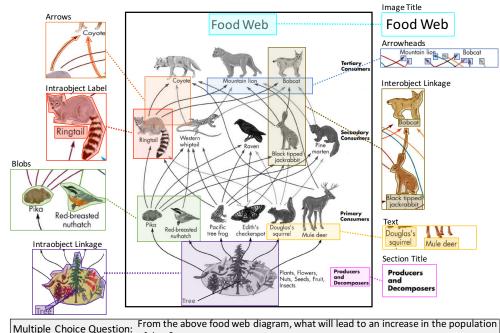

- Video games
- Pathing / routing problems
- Resource planning problems
- Robot motion planning
- Language analysis
- Machine translation
- Speech recognition
- O ...

### A\* in Recent Literature

 Joint A\* CCG Parsing and Semantic Role Labeling (EMLN'15)

Diagram Understanding (ECCV'17)

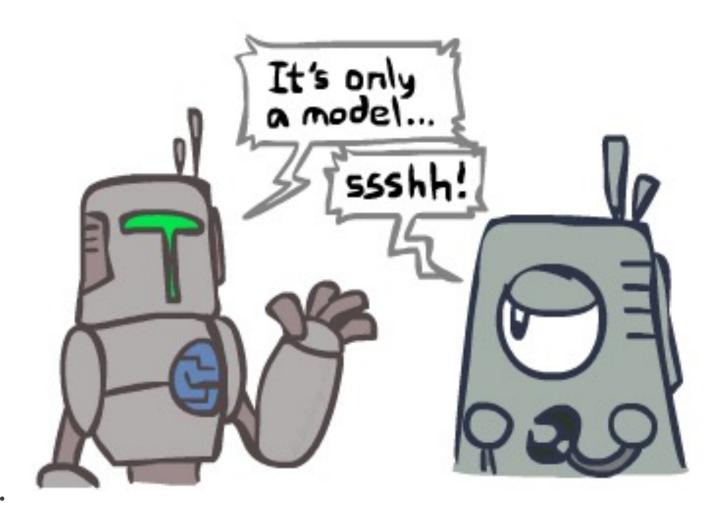

of deer? a) increase in lion b) decrease in plants c) decrease in lion d) increase in pika

### Search and Models

- Search operates over models of the world
  - The agent doesn't actually try all the plans out in the real world!
  - o Planning is all "in simulation"
  - Your search is only as good as your models...

# Search Gone Wrong?
