INFERENCE IN BAYESIAN NETWORKS

AIMA2E CHAPTER 14.4-5

Inference by enumeration

Slightly intelligent way to sum out variables from the joint without actually constructing its explicit representation ${\sf S}$

Simple query on the burglary network:

 $\begin{aligned} &\mathbf{P}(B|j,m) \\ &= \mathbf{P}(B,j,m)/P(j,m) \\ &= \alpha \mathbf{P}(B,j,m) \\ &= \alpha \Sigma_e \Sigma_a \mathbf{P}(B,e,a,j,m) \end{aligned}$

Rewrite full joint entries using product of CPT entries:

 $\mathbf{P}(B|j,m)$

 $=\alpha\sum_{e}\sum_{a}\mathbf{P}(B)P(e)\mathbf{P}(a|B,e)P(j|a)P(m|a)$

 $= \alpha \mathbf{P}(B) \sum_{e} P(e) \sum_{a} \mathbf{P}(a|B,e) P(j|a) P(m|a)$

Recursive depth-first enumeration: O(n) space, $O(d^n)$ time

AlM A2e Chapter 14.4-5 4

Outline

- ♦ Exact inference by enumeration
- ♦ Exact inference by variable elimination
- \diamondsuit Approximate inference by stochastic simulation
- ♦ Approximate inference by Markov chain Monte Carlo

AlM A2e Chapter 14.4-5 2

AlM A2e Chapter 14.4-5 1

Enumeration algorithm

function ENUMERATION-ASK (X, \mathbf{e}, bn) returns a distribution over X

 \mathbf{inputs} : X, the query variable

 ${f e}$, observed values for variables ${f E}$

 bn , a Bayesian network with variables $\{X\} \, \cup \, \mathbf{E} \, \cup \, \mathbf{Y}$

 $\mathbf{Q}(X) \leftarrow$ a distribution over X, initially empty

for each value x_i of X do

extend ${f e}$ with value x_i for X

 $\mathbf{Q}(x_i) \leftarrow \text{Enumerate-All(Vars[bn], e)}$

return NORMALIZE(Q(X))

 $\mathbf{function} \ \mathbf{Enumerate-All}(\mathit{vars}, \mathbf{e}) \ \mathbf{returns} \ \mathsf{a} \ \mathsf{real} \ \mathsf{number}$

if EMPTY? (vars) then return 1.0

 $Y \leftarrow \text{First}(vars)$

 $\mathbf{if}\ Y$ has value y in \mathbf{e}

then return $P(y \mid Pa(Y)) \times \text{Enumerate-All(Rest(vars), e)}$

else return Σ_y $P(y \mid Pa(Y)) \times \text{Enumerate-All(Rest(vars), e}_y)$

where \mathbf{e}_y is \mathbf{e} extended with $Y=\ y$

AlM A2e Chapter 14.4-5 5

Inference tasks

Simple queries: compute posterior marginal $\mathbf{P}(X_i|\mathbf{E}=\mathbf{e})$ e.g., P(NoGas|Gauge=empty,Lights=on,Starts=false)

Conjunctive queries: $P(X_i, X_j | E = e) = P(X_i | E = e)P(X_j | X_i, E = e)$

Optimal decisions: decision networks include utility information; probabilistic inference required for P(outcome|action, evidence)

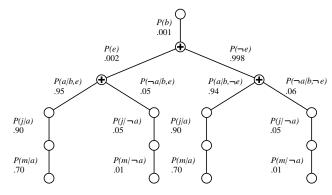

Value of information: which evidence to seek next?

Sensitivity analysis: which probability values are most critical?

Explanation: why do I need a new starter motor?

Evaluation tree

Enumeration is inefficient: repeated computation e.g., computes P(j|a)P(m|a) for each value of e

AIMA2e Chapter 14.4-5 3 AIMA2e Chapter 14.4-5 6

Inference by variable elimination

Variable elimination: carry out summations right-to-left, storing intermediate results (factors) to avoid recomputation

$$\begin{split} \mathbf{P}(B|j,m) &= \alpha \underbrace{\mathbf{P}(B)}_{B} \underbrace{\Sigma_{e} \underbrace{P(e)}_{E} \underbrace{\Sigma_{a}}_{A} \underbrace{\mathbf{P}(a|B,e)}_{A} \underbrace{P(j|a)}_{J} \underbrace{P(m|a)}_{M} \\ &= \alpha \mathbf{P}(B) \underbrace{\Sigma_{e} P(e)}_{E} \underbrace{\Sigma_{a}}_{A} \mathbf{P}(a|B,e) P(j|a) f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\Sigma_{e} P(e)}_{E} \underbrace{\Sigma_{a}}_{A} P(a|B,e) f_{J}(a) f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\Sigma_{e} P(e)}_{E} \underbrace{\Sigma_{a}}_{A} f_{A}(a,b,e) f_{J}(a) f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\Sigma_{e}}_{E} P(e) \underbrace{f_{\bar{A}JM}(b,e)}_{A} \text{ (sum out } A \text{)} \\ &= \alpha \mathbf{P}(B) f_{\bar{E}\bar{A}JM}(b) \text{ (sum out } E \text{)} \\ &= \alpha f_{B}(b) \times f_{\bar{E}\bar{A}JM}(b) \end{split}$$

AlM A2e Chapter 14.4-5 7

Irrelevant variables

Consider the query P(JohnCalls|Burglary = true)

 $P(J|b) = \alpha P(b) \mathop{}_{\tilde{e}} P(e) \mathop{}_{\tilde{a}} P(a|b,e) P(J|a) \mathop{}_{\tilde{m}} P(m|a)$

Sum over m is identically 1; M is irrelevant to the query

Thm 1: Y is irrelevant unless $Y \in Ancestors(\{X\} \cup \mathbf{E})$

Here, X=JohnCalls, $\mathbf{E}=\{Burglary\}$, and $Ancestors(\{X\}\cup\mathbf{E})=\{Alarm,Earthquake\}$ so M is irrelevant

(Compare this to backward chaining from the query in Horn clause KBs)

AlM A2e Chapter 14, 4-5 18

Variable elimination: Basic operations

Summing out a variable from a product of factors:
move any constant factors outside the summation
add up submatrices in pointwise product of remaining factors

$$\sum_{x} f_1 \times \cdots \times f_k = f_1 \times \cdots \times f_i \sum_{x} f_{i+1} \times \cdots \times f_k = f_1 \times \cdots \times f_i \times f_{\bar{X}}$$

assuming f_1, \ldots, f_i do not depend on X

Pointwise product of factors f_1 and f_2 :

 $f_1(x_1, \dots, x_j, y_1, \dots, y_k) \times f_2(y_1, \dots, y_k, z_1, \dots, z_l)$ $= f(x_1, \dots, x_j, y_1, \dots, y_k, z_1, \dots, z_l)$ E.g., $f_1(a, b) \times f_2(b, c) = f(a, b, c)$

AlM A2e Chapter 14.4-5 8

Irrelevant variables contd.

Defn: moral graph of Bayes net: marry all parents and drop arrows

Defn: A is m-separated from B by C iff separated by C in the moral graph

Thm 2: Y is irrelevant if m-separated from X by ${\bf E}$

For P(JohnCalls|Alarm=true), both Burglary and Earthquake are irrelevant

AlM A2e Chapter 14.4-5 11

Variable elimination algorithm

 $\begin{array}{ll} \mathbf{function} \ \ \mathbf{ELIMINATION-Ask}\big(X,\mathbf{e},\,bn\big) \ \mathbf{returns} \ \mathsf{a} \ \mathsf{distribution} \ \mathsf{over} \ X \\ \mathbf{inputs} \colon X, \ \mathsf{the} \ \mathsf{query} \ \mathsf{variable} \end{array}$

e, evidence specified as an event

 bn , a belief network specifying joint distribution $\mathbf{P}(X_1,\ldots,X_n)$

 $factors \leftarrow [\]; \ vars \leftarrow \texttt{Reverse}\big(\texttt{Vars}[bn]\big)$

for each var in vars do

 $factors \leftarrow [\texttt{Make-Factor}(var, \mathbf{e})|factors]$

if var is a hidden variable then $factors \leftarrow \text{Sum-Out}(var, factors)$

return Normalize(Pointwise-Product(factors))

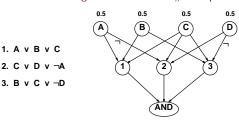

Complexity of exact inference

Singly connected networks (or polytrees):

- any two nodes are connected by at most one (undirected) path
- time and space cost of variable elimination are $O(d^k n)$

Multiply connected networks:

- can reduce 3SAT to exact inference \Rightarrow NP-hard
- equivalent to counting 3SAT models ⇒ #P-complete

AlM A2e Chapter 14.4-5 9 AlM A2e Chapter 14.4-5 12

Inference by stochastic simulation

Basic idea:

- 1) Draw N samples from a sampling distribution S
- 2) Compute an approximate posterior probability \hat{P}
- 3) Show this converges to the true probability ${\cal P}$

Coin

Outline:

- Sampling from an empty network
- Rejection sampling: reject samples disagreeing with evidence
- Likelihood weighting: use evidence to weight samples
- Markov chain Monte Carlo (MCMC): sample from a stochastic process whose stationary distribution is the true posterior

AlM A2e Chapter 14, 4-5 13

Example P(C) .50 $C \mid P(S|C)$ C | P(R|C)Rain .10 T Sprinkler Т .80 F .50 F .20 Wet Grass R | P(W|S,R)T T F.90 $F \quad T$.90 F F .01

AlM A2e Chapter 14.4-5 16

Sampling from an empty network

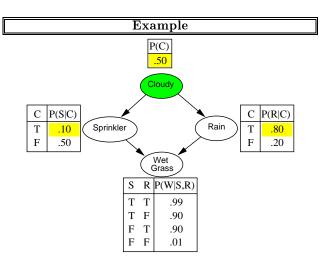

function PRIOR-SAMPLE(bn) returns an event sampled from bn inputs: bn, a belief network specifying joint distribution $\mathbf{P}(X_1,\ldots,X_n)$

 $\mathbf{x} \leftarrow$ an event with n elements

for i = 1 to n do

 $x_i \!\leftarrow\! \mathsf{a} \; \mathsf{random} \; \mathsf{sample} \; \mathsf{from} \; \mathbf{P}(X_i \mid Parents(X_i))$

 $\mathbf{return}\ \mathbf{x}$

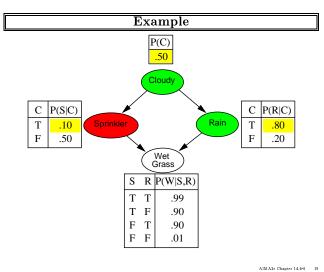

AlM A2e Chapter 14.4-5 17

AlM A2e Chapter 14.4-5 14

Sampling from an empty network contd.

Probability that PRIORSAMPLE generates a particular event $S_{PS}(x_1\dots x_n)=\prod_{i=1}^n P(x_i|Parents(X_i))=P(x_1\dots x_n)$ i.e., the true prior probability

E.g., $S_{PS}(t, f, t, t) = 0.5 \times 0.9 \times 0.8 \times 0.9 = 0.324 = P(t, f, t, t)$

Let $N_{PS}(x_1\dots x_n)$ be the number of samples generated for event x_1,\dots,x_n

Then we have

$$\lim_{N \to \infty} \hat{P}(x_1, \dots, x_n) = \lim_{N \to \infty} N_{PS}(x_1, \dots, x_n)/N$$

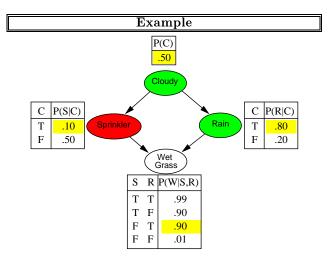

$$= S_{PS}(x_1, \dots, x_n)$$

$$= P(x_1 \dots x_n)$$

That is, estimates derived from PRIORSAMPLE are consistent

Shorthand: $\hat{P}(x_1, \ldots, x_n) \approx P(x_1 \ldots x_n)$

AlM A2e Chapter 14, 4-5 22

AlM A2e Chapter 14.4-5 28

Rejection sampling

 $\hat{\mathbf{P}}(X|\mathbf{e})$ estimated from samples agreeing with \mathbf{e}

function REJECTION-SAMPLING(X, e, bn, N) returns an estimate of P(X|e) local variables: N, a vector of counts over X, initially zero for j=1 to N do $\mathbf{x} \leftarrow \text{PRIOR-SAMPLE}(bn)$ if \mathbf{x} is consistent with e then $N[x] \leftarrow N[x] + 1 \text{ where } x \text{ is the value of } X \text{ in } \mathbf{x}$ return NORMALIZE(N[X])

E.g., estimate $\mathbf{P}(Rain|Sprinkler=true)$ using 100 samples 27 samples have Sprinkler=true

Of these, 8 have Rain = true and 19 have Rain = false.

 $\hat{\mathbf{P}}(Rain|Sprinkler=true) = \mathbf{Normalize}(\langle 8, 19 \rangle) = \langle 0.296, 0.704 \rangle$

Similar to a basic real-world empirical estimation procedure

AlM A2e Chapter 14.4-5 23

Example P(C) .50 Cloudy $C \mid P(S|C)$ C | P(R|C)Rain Sprinkler T .10 T .80 F .20 .50 S R | P(W|S,R)T T .99 T F.90 F T .90 F F .01

Analysis of rejection sampling

$$\begin{split} \mathbf{P}(X|\mathbf{e}) &= \alpha \mathbf{N}_{PS}(X,\mathbf{e}) & \text{(algorithm defn.)} \\ &= \mathbf{N}_{PS}(X,\mathbf{e})/N_{PS}(\mathbf{e}) & \text{(normalized by } N_{PS}(\mathbf{e})) \\ &\approx \mathbf{P}(X,\mathbf{e})/P(\mathbf{e}) & \text{(property of PriorSample)} \\ &= \mathbf{P}(X|\mathbf{e}) & \text{(defn. of conditional probability)} \end{split}$$

Hence rejection sampling returns consistent posterior estimates

Problem: hopelessly expensive if $P(\mathbf{e})$ is small

 $P(\mathbf{e})$ drops off exponentially with number of evidence variables!

AIMA2e Chapter 14.45 21 AIMA2e Chapter 14.45 22

Likelihood weighting

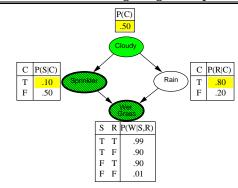

Idea: fix evidence variables, sample only nonevidence variables, and weight each sample by the likelihood it accords the evidence

```
function LIKELIHOOD-WEIGHTING (X, \mathbf{e}, bn, N) returns an estimate of P(X|\mathbf{e}) local variables: \mathbf{W}, a vector of weighted counts over X, initially zero for j=1 to N do \mathbf{x}, w \leftarrow \text{WEIGHTED-SAMPLE}(bn) \mathbf{W}[x] \leftarrow \mathbf{W}[x] + w where x is the value of X in \mathbf{x} return NORMALIZE(\mathbf{W}[X]) \mathbf{W}[x] \leftarrow \mathbf{W}[x] + \mathbf{w} where x = \mathbf{w} is the value of x = \mathbf{w} in \mathbf{w} return NORMALIZE(\mathbf{W}[X]) \mathbf{W}[x] \leftarrow \mathbf{W}[x] + \mathbf{w} where x = \mathbf{w} is the value of x = \mathbf{w} in x = \mathbf{w} an event with x = \mathbf{w} elements; x \leftarrow \mathbf{w} and x = \mathbf{w} in x = \mathbf{w
```

AlM A2e Chapter 14.4-5 25

AlM A2e Chapter 14.4-5 26

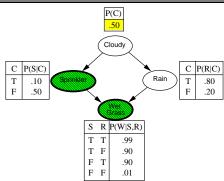

Likelihood weighting example

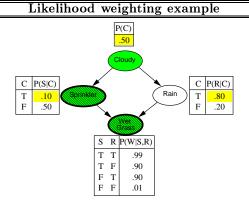

w = 1.0

AlM A2e Chapter 14, 4-5 28

Likelihood weighting example

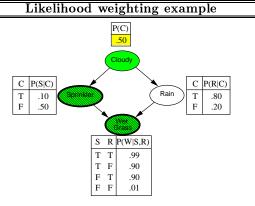

w = 1.0

 $w = 1.0 \times 0.1$

AlM A2e Chapter 14.4-5 29

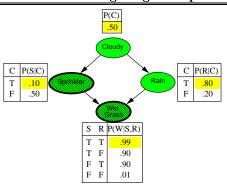

w = 1.0

Likelihood weighting example

 $w = 1.0 \times 0.1$

Likelihood weighting example

 $w = 1.0 \times 0.1$

AlM A2e Chapter 14.4-5 31

Approximate inference using MCMC

"State" of network = current assignment to all variables.

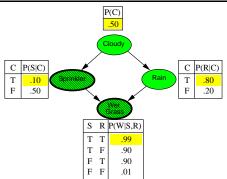

Generate next state by sampling one variable given Markov blanket Sample each variable in turn, keeping evidence fixed

function MCMC-Ask(X, e, bn, N) returns an estimate of $P(X|\mathbf{e})$ local variables: $\mathbf{N}[X]$, a vector of counts over X, initially zero Z, the nonevidence variables in bn \mathbf{x} , the current state of the network, initially copied from \mathbf{e} initialize \mathbf{x} with random values for the variables in \mathbf{Y} for j=1 to N do $\mathbf{N}[x]\leftarrow\mathbf{N}[x]+1$ where x is the value of X in \mathbf{x} for each Z_i in \mathbf{Z} do sample the value of Z_i in \mathbf{x} from $\mathbf{P}(Z_i|MB(Z_i))$ given the values of $MB(Z_i)$ in \mathbf{x} return $NORMALIZE(\mathbf{N}[X])$

Can also choose a variable to sample at random each time

AlM A2e Chapter 14.4-5 34

Likelihood weighting example

 $w = 1.0 \times 0.1 \times 0.99 = 0.099$

AlM A2e Chapter 14.4-5 32

The Markov chain

With Sprinkler = true, WetGrass = true, there are four states:

Wander about for a while, average what you see

AlM A2e Chapter 14, 4-5 35

Likelihood weighting analysis

Sampling probability for $\mathbf{Weighted}\mathbf{Sample}$ is

 $S_{WS}(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{l} P(z_i | Parents(Z_i))$

Note: pays attention to evidence in **ancestors** only ⇒ somewhere "in between" prior and

posterior distribution

Sprinkler Rain

Weight for a given sample \mathbf{z}, \mathbf{e} is

 $w(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{m} P(e_i | Parents(E_i))$

Weighted sampling probability is

 $S_{WS}(\mathbf{z}, \mathbf{e})w(\mathbf{z}, \mathbf{e})$

 $= \prod_{i=1}^{l} P(z_i|Parents(Z_i)) \quad \prod_{i=1}^{m} P(e_i|Parents(E_i))$

 $=P(\mathbf{z},\mathbf{e})$ (by standard global semantics of network)

Hence likelihood weighting returns consistent estimates but performance still degrades with many evidence variables because a few samples have nearly all the total weight

MCMC example contd.

Estimate P(Rain|Sprinkler = true, WetGrass = true)

Sample Cloudy or Rain given its Markov blanket, repeat. Count number of times Rain is true and false in the samples.

E.g., visit 100 states

31 have Rain = true, 69 have Rain = false

 $\hat{\mathbf{P}}(Rain|Sprinkler = true, WetGrass = true) = Normalize(\langle 31, 69 \rangle) = \langle 0.31, 0.69 \rangle$

Theorem: chain approaches stationary distribution: long-run fraction of time spent in each state is exactly proportional to its posterior probability

AIM A2e Chapter 14.4-5 33 AIM A2e Chapter 14.4-5 36

Markov blanket sampling

Markov blanket of Cloudy is $Sprinkler \ {\bf and} \ Rain$ Markov blanket of Rain is Cloudy, Sprinkler, and WetGrass

Probability given the Markov blanket is calculated as follows: $P(x_i'|MB(X_i)) = P(x_i'|Parents(X_i))\prod_{Z_i \in Children(X_i)} P(z_j|Parents(Z_j))$

Easily implemented in message-passing parallel systems, brains

Main computational problems:

- 1) Difficult to tell if convergence has been achieved
- 2) Can be wasteful if Markov blanket is large: $P(X_i|MB(X_i))$ won't change much (law of large numbers)

AlM A2e Chapter 14.4-5 37

Summary

Exact inference by variable elimination:

- polytime on polytrees, NP-hard on general graphs
 space = time, very sensitive to topology

Approximate inference by LW, MCMC:

- LW does poorly when there is lots of (downstream) evidence
- LW, MCMC generally insensitive to topology
- Convergence can be very slow with probabilities close to $\boldsymbol{1}$ or $\boldsymbol{0}$
- Can handle arbitrary combinations of discrete and continuous variables

AlM A2e Chapter 14.4-5 38
