CSE 333

Lecture 13 - constructor insanity

Steve Gribble

Department of Computer Science & Engineering

University of Washington

Today's goals

More details on constructors, destructors, operators

Walk through *complex_example/*

- pretty hairy and complex
- a lesson on why using a **subset of C++** is often better

new / delete / delete[ ]

Constructors

A *constructor* initializes a newly instantiated object

- a class can have multiple constructors
  - they differ in the arguments that they accept
  - which one is invoked depends on how the object is instantiated

You can write constructors for your object

- but if you don't write any, C++ might automatically synthesize a *default constructor* for you
  - the default constructor is one that takes no arguments and that initializes all member variables to 0-equivalents (0, NULL, false, ..)
  - C++ does this iff your class has no const or reference data members

Example of synthesis

see SimplePoint.cc, SimplePoint.h

Constructors, continued

You might choose to define multiple constructors:

```
Point::Point() {
  x_ = 0;
  y_ = 0;
}

Point::Point(const int x, const int y) {
  x_ = x;
  y_ = y;
}

void foo() {
  Point x;  // invokes the default (argument-less) constructor
  Point y(1,2);  // invokes the two-int-arguments constructor
}
```

Constructors, continued

You might choose to define only one:

```
Point::Point(const int x, const int y) {
  x_ = x;
  y_ = y;
}

void foo() {
  // Compiler error; if you define any constructors, C++ will
  // not automatically synthesize a default constructor for you.
  Point x;

  // Works.
  Point y(1,2);  // invokes the two-int-arguments constructor
}
```

Initialization lists

As shorthand, C++ lets you declare an initialization list as part of your constructor declaration

- initializes fields according to parameters in the list
- the following two are (nearly) equivalent:

```
Point::Point(const int x, const int y) : x_(x), y_(y) {
  std::cout << "Point constructed: (" << x_ << ",";
  std::cout << y_ << ")" << std::endl;
}
```

```
Point::Point(const int x, const int y) {
  x_ = x;
  y_ = y;
  std::cout << "Point constructed: (" << x_ << ",";
  std::cout << y_ << ")" << std::endl;
}
```

Copy constructors

C++ has the notion of a **copy constructor**

- used to **create a new object** as a copy of an existing object

```
Point::Point(const int x, const int y) : x_(x), y_(y) { }

Point::Point(const Point &copyme) {  // copy constructor
  x_ = copyme.x_;
  y_ = copyme.y_;
}

void foo() {
  // invokes the two-int-arguments constructor
  Point x(1,2);

  // invokes the copy constructor to construct y as a copy of x
  Point y(x);  // could also write as "Point y = x;"
}
```

When do copies happen?

The copy constructor is invoked if:

- you pass an object as an parameter to a call-by-value function

```
void foo(Point x) { ... }

Point y;  // default cons.
foo(y);   // copy cons.
```

- you return an object from a function

```
Point foo() {
  Point y;  // default cos.
  return y; // copy cons.
}
```

- you initialize an object from another object of the same type

```
Point x;   // default cons.
Point y(x);  // copy cons.
Point z = y; // copy cons.
```

But…the compiler is smart…

It sometimes uses a "return by value optimization" to eliminate unnecessary copies

- sometimes you might not see a constructor get invoked when you expect it

```
Point foo() {
  Point y;  // default constructor.
  return y; // copy constructor?  optimized?
}

Point x(1,2);     // two-ints-argument constructor.
Point y = x;      // copy constructor.
Point z = foo();  // copy constructor? optimized?
```

Synthesized copy constructor

If you don't define your own copy constructor, C++ will synthesize one for you

- it will do a shallow copy of all of the fields (i.e., member variables) of your class
- sometimes the right thing, sometimes the wrong thing

see SimplePoint.cc, SimplePoint.h

assignment != construction

The "=" operator is the assignment operator

- assigns values to an existing, already constructed object
- you can overload the "=" operator

```
Point w;            // default constructor.
Point x(1,2);       // two-ints-argument constructor.
Point y = w;        // copy constructor.
y = x;              // assignment operator.
```

Overloading the "=" operator

You can choose to overload the "=" operator

- but there are some rules you should follow

```
Point &Point::operator=(const Point& rhs) {
  if (this != &rhs) {  // always check against this
    x_ = rhs.x_;
    y_ = rhs.y_;
  }
  return *this;  // always return *this from =
}

Point a;       // default constructor
a = b = c;     // works because "=" returns *this
a = (b = c);   // equiv to above, as "=" is right-associative
(a = b) = c;   // works because "=" returns a non-const
```

Synthesized assignment oper.

If you don't overload the assignment operator, C++ will synthesize one for you

- it will do a shallow copy of all of the fields (i.e., member variables) of your class
- sometimes the right thing, sometimes the wrong thing

see SimplePoint.cc, SimplePoint.h

*see complex_example/**

Dealing with the insanity

C++ style guide tip

- if possible, disable the copy const. and assignment operator
  - *not possible if you want to store objects of your class in an STL container, unfortunately*

```
class Point {
 public:
  Point(int x, int y) : x_(x), y_(y) { }

 private:
  // disable copy cons. and "=" by declaring but not defining
  Point(Point &copyme);
  Point &operator=(Point &rhs);
};

Point w;          // compiler error
Point x(1,2);     // OK
Point y = x;      // compiler error
x = w;            // compiler error
```

Dealing with the insanity

C++ style guide tip

- if you disable them, then you should instead have an explicit "CopyFrom" function

Point.cc, h

```
class Point {
 public:
  Point::Point(int x, int y) : x_(x), y_(y) { }
  void CopyFrom(const Point &copy_from_me);

 private:
  // disable copy cons. and "=" by declaring but not defining
  Point(const Point &copyme);
  Point &operator=(const Point &rhs);
};
```

sanepoint.cc

```
Point x(1,2);          // OK
Point y(3,4);          // OK
x.CopyFrom(y);         // OK
```

new

To allocate on the heap using C++, you use the “new” keyword instead of the “malloc( )” stdlib.h function

- you can use new to allocate an object
- you can use new to allocate a primitive type

To deallocate a heap-allocated object or primitive, use the “delete” keyword instead of the “free( )” stdlib.h function

- if you’re using a legacy C code library or module in C++
  - if C code returns you a malloc( )’d pointer, use free( ) to deallocate it
  - never free( ) something allocated with new
  - never delete something allocated with malloc( )

new / delete

see heappoint.cc

Dynamically allocated arrays

To dynamically allocate an array

- use "`type *name = new type[size];`"

To dynamically deallocate an array

- use "`delete[] name;`"
- it is an error to use "`delete name;`" on an array
  - the compiler probably won't catch this, though!!!
  - it can't tell if it was allocated with "`new type[size];`" or "`new type;`"

see arrays.cc

malloc vs. new

	malloc( )	**new**
what is it	a function	an operator and keyword
how often used in C	often	never
how often used in C++	rarely	often
allocates memory for	anything	arrays, structs, objects, primitives
returns	a (void *) *(needs a cast)*	appropriate pointer type *(doesn't need a cast)*
when out of memory	returns NULL	throws an exception
deallocating	free	delete or delete[ ]

Overloading the "=" operator

Remeber the rules we should follow?

- here's why; hugely subtle bug

```
Foo::Foo(int val) { Init(val); }
Foo::~Foo() { delete my_ptr_; }

void Foo::Init(int val) { my_ptr_ = new int; *my_ptr_ = val; }

Foo &Foo::operator=(const Foo& rhs) {
  // bug...we forgot our "if (self == &rhs) { ... }" guard
  delete my_ptr_;
  Init(*(rhs.my_ptr_));  // might crash here (see below)
  return *this;  // always return *this from =
}

void bar() {
  Foo a(10);  // default constructor
  Foo b(20);  // default constructor
  a = b;      // crash above; dereference delete'd pointer!!
}
```

Overloading the "=" operator

Remeber the rules we should follow?

- here's why; hugely subtle bug

This is yet another reason for disabling the assignment operator, when possible!!

Exercise 1

Modify your 3D Point class from lec12 exercise 1

- disable the copy constructor and assignment operator
- attempt to use copy & assign in code, and see what error the compiler generates
- write a CopyFrom( ) member function, and try using it instead

Exercise 2

Write a C++ class that:

- is given the name of a file as a constructor argument
- has a “GetNextWord( )” method that returns the next whitespace or newline-separate word from the file as a copy of a “string” object, or an empty string once you hit EOF.
- has a destructor that cleans up anything that needs cleaning up

Exercise 3

Write a C++ function that:

- uses new to dynamically allocate an array of strings
  - and uses delete[ ] to free it
- uses new to dynamically allocate an array of pointers to strings
  - and then iterates through the array to use new to allocate a string for each array entry and to assign to each array element a pointer to the associated allocated string
  - and then uses delete to delete each allocated string
  - and then uses delete[ ] to delete the string pointer array
  - (whew!)

See you on Friday!
