

# Control flow 

Michael Ernst
UW CSE 140
Winter 2013

## Repeating yourself

Making decisions

## Temperature conversion chart

Recall exercise from previous lecture

```
fahr = 30
cent = (f-32)/9.0*5
print fahr, cent
fahr = 40
cent = (f-32)/9.0*5
print fahr, cent
fahr = 50
cent = (f-32)/9.0*5
print fahr, cent
fahr = 60
cent = (f-32)/9.0*5
print fahr, cent
fahr = 70
cent = (f-32)/9.0*5
print fahr, cent
print "All done"
```

Output:
30-1.11
404.44
5010.0
6015.56
7021.11

All done

## Temperature conversion chart

A better way to repeat yourself:

## How a loop is executed: Transformation approach

Idea: convert a for loop into something we know how to execute

1. Evaluate the sequence expression
2. Write an assignment to the loop variable, for each sequence element
3. Write a copy of the loop after each assignment
4. Execute the resulting statements

## How a loop is executed: Direct approach

1. Evaluate the sequence expression
2. While there are sequence elements left:
a) Assign the loop variable to the next remaining sequence element
b) Execute the loop body

## The body can be multiple statements

Execute whole body, then execute whole body again, etc.
for i in [3,4,5]:

Convention: often use ior j as loop variable This is an exception to the rule that variable names should be descriptive

## Indentation is significant

- Every statement in the body must have exactly the same indentation
- That's how Python knows where the body ends
for in in, 4,5]:
print "Start body"
Error! [print i print i*i
- Compare the results of these loops:
for $f$ in $[30,40,50,60,70]$ : print f, (f-32)/9.0*5
print "All done"
for $f$ in $[30,40,50,60,70]:$
print f, (f-32)/9.0*5
print "All done"

## The body can be multiple statements

How many statements does this loop contain?

| for i in [0,1]: |  | $\frac{\text { Output: }}{\text { Outer 0 }}$ |
| :---: | :---: | :---: |
| print "Outer", ifor j in $[2,3]:$"nested"$\left.\begin{array}{l}\text { loop pody: } \\ \text { 2statements }\end{array}\right\}$print " Inner", j <br> print " Sum", i+j <br> print "Outer", $i$ | loop body: 3 statements | Inner 2 |
|  |  | Sum 2 |
|  |  | Inner 3 |
|  |  | Sum 3 |
|  |  | Outer 0 |
|  |  | Outer 1 |
|  |  | Inner 2 |
|  |  | Sum 3 |
|  |  | Inner 3 |
|  |  | Sum 4 |
| What is the output? |  | Outer 1 |

## Understand loops through the transformation approach

Key idea:

1. Assign each sequence element to the loop variable
2. Duplicate the body
```
for i in [0,1]: i = 0 i = 0
    print "Outer", i print "Outer", i print "Outer", i
    for j in [2,3]: for j in [2,3]:
        print " Inner", j
            print " Inner", j
            i = 1
            print "Outer", i print " Inner", j
            for j in [2,3]: i = 1
    print " Inner", j print "Outer", i
for j in [2,3]:
    print " Inner", j
```

## Fix this loop

```
# Goal: print 1, 2, 3, ..., 48, 49, 50
for tens_digit in [0, 1, 2, 3, 4]:
    for ones_digit in [1, 2, 3, 4, 5, 6, 7, 8, 9]:
        print tens_digit * 10 + ones_digit
```

What does it actually print?
How can we change it to correct its output?

Moral: Watch out for edge conditions (beginning or end of loop)

## Test your understanding of loops

## Puzzle 1:

## Output:

for $i$ in $[0,1]:$ print i

0
1
print i 1
Puzzle 2:
$i=5$
for i in []:
(no output)
print i
Puzzle 3:

> Reusing loop variable (don't do this!)
for i in [0,1]:
 for i in [2,3]:
print " Inner", i] loop $\left.\begin{array}{l}\text { inner } \\ \text { body }\end{array}\right]$ loop

## The range function

A typical for loop does not use an explicit list:

for $i$ in range (5) $\underset{\substack{\text { The list } \\[0,1,2,3,4]}}{\substack{\text { an }}}$
... body Upper limit
(exclusive)
range (5) $=[0,1,2,3,4]$

| $\begin{array}{c}\text { Lowerl limit } \\ \text { (inclusive }\end{array}$ |
| :--- |

range (1,5) $=[1,2,3,4]$
step (distance
between elements)
range $(1,10,2)=[1,3,5,7,9]$

## Decomposing a list computation

- To compute a value for a list:
- Compute a partial result for all but the last element
- Combine the partial result with the last element

Example: sum of a list:
$[3,1,4,1,5,9,2,6,5$ ]

```
sum(List a) = sum(List a) +5
sum}(\mathrm{ List b) =sum (List c) + 6
sum(List y) = sum(List z) + 3
sum(empty list) = 0
```

## How to process a list: One element at a time

- A common pattern when processing a list:

```
# Sum of a list
result = 0
for element in mylist:
                        result = result + element
```

... use result

- initial_value is a correct result for an empty list
- As each element is processed, result is a correct result for a prefix of the list
- When all elements have been processed, result is a correct result for the whole list

## Examples of list processing

- Product of a list:
result = 1

```
result = initial_value
for element in list:
    result = updated result
```

    for element in mylist:
        result \(=\) result \(*\) element
    - Maximum of a list:
result $=$ mylist[0〕

The first element of the list (counting from zero)
for element in mylist:

```
result = max(result, element)
```

- Approximate the value 3 by $1+2 / 3+4 / 9+8 / 27+16 / 81+\ldots$

$$
=(2 / 3)^{0}+(2 / 3)^{1}+(2 / 3)^{2}+(2 / 3)^{3}+\ldots+(2 / 3)^{10}
$$

$$
\text { result }=0
$$

for element in range(11):
result $=$ result $+(2.0 / 3.0) * * e l e m e n t$

## Making decisions

- How do we compute absolute value? abs(5) $=5$ abs(0) $=0$ abs(-22) $=22$

## Absolute value solution

If the value is negative, negate it.
Otherwise, use the original value.

```
val = -10
if val < 0:
    result = - val
else:
    result = val
print result
```

val $=-10$
if val < $0:$
print - val
else:
print val

## The if body can be any statements

## The then clause or the else clause is executed

if is_prime(x):

$$
y=x / 0
$$

else

$$
\mathbf{y}=x * x
$$
