Outline for Today

- Iteration – repeating operations
- Iteration in Java – while statement
- Shorthand for definite (counting) iterations – for statement
- Nested loops

Programming a Teller Machine

- Suppose you are working on the code for a automated teller machine (ATM). Your code should give out the right number of bills when the user withdraws money. The ATM contains \$20 and \$5 bills.
- Problem: Hand out the right number of \$20 and \$5 bills to make up d dollars. Assume that d is a multiple of \$5.
 - Best solution would use as many \$20s as possible
 - Design an algorithm for this with your neighbors

Iteration/Repetition

- The ATM cash algorithm is an example of an *iteration* or repetition – repeatedly perform some operation
- A few more examples
 - Bake the roast until it has an internal temperature of 220 degrees
 - While there are still donuts in the box, eat one
 - Lather, rinse, repeat
 - Simulations/games – science, entertainment
 - Repeatedly update actions of objects in the simulation
 - Video – display frames repeatedly

Iteration in Java

- Basic form – while statement

```
while ( condition ) {  
    list of statements  
}
```

- Terminology

- *condition* is sometimes called the loop condition
- *list of statements* is often called the loop body

I-7

Iteration in Java

- Meaning of

```
while ( condition ) {  
    list of statements  
}
```

- Repeatedly do the following:

- Evaluate the *condition*
- If the *condition* is false, the loop terminates – continue with the statement following the loop body (after '}')
- Execute the list of statements and repeat

- Note: condition is only reevaluated after finishing the *complete* execution of the loop body – not concurrently as loop body statements are executed

Exercise – Write Numbers and Squares

- Suppose we want to write a table of numbers and their squares for the numbers 1 to 5

- Brute force ("+" used to combine strings)

```
System.out.println(1 + " squared = " + 1*1);  
System.out.println(2 + " squared = " + 2*2);  
System.out.println(3 + " squared = " + 3*3);  
System.out.println(4 + " squared = " + 4*4);  
System.out.println(5 + " squared = " + 5*5);
```

- How could we improve this?

I-10

What We're Really Trying to Do

- We really want to repeatedly execute

```
System.out.println(k + " squared = " + k*k);
```

with k taking on the values 1 through 5 on successive repetitions

- Solution (?)

```
k = 1;  
while (k <= 5) {  
    System.out.println(k + " squared = " + k*k);  
}
```

- Does this work? How can we tell?

I-11

Tracing Loops

- You can "desk-check" a loop (or other code) by hand simulating the steps the computer performs

I-12

Exercise

- In arithmetic, $n!$ ("n factorial") is defined to be $1 * 2 * 3 * 4 * \dots * (n-1) * n$
- Exercise: write a loop to compute $7!$ and check it
 - Hint(?): try writing this out by hand, then figure out what statements can be repeated while some values in them change

Counting Loops – For Statement

- The loops we've seen so far all execute a *definite* number of times with some variable taking on a sequence of values
- Java, like most other languages, provides a special statement to make this convenient – the for statement

```
for (initialization; condition; update) {  
    list of statements  
}
```

1/26/2003

(c) 2003 - University of Washington

I-16

Counting Loops

- Example: Print the numbers 1 through 100
 - With a while loop

```
int k = 1;  
while (k <= 100) {  
    System.out.println(k);  
    k = k + 1;  
}
```
 - With a for loop

```
for (int k = 1; k <= 10; k = k + 1) {  
    System.out.println(k);  
}
```
- These mean exactly the same thing

I-17

For Loops and While Loops

- A for statement is a convenient shorthand for an equivalent while statement

```
for (initialization; condition; update) {  
    list of statements  
}
```

has ^(for our purposes) exactly the same meaning as

```
while ( condition ) {  
    list of statements  
    update  
}
```
- Note that the update executes after the loop body

Factorial as a Method

- A calculation like factorial is a logically coherent operation. It makes sense to package it as a method. Complete the implementation below using a for statement

```
/** Return the value n! */  
public int factorial(int n) {
```

```
}
```

1/26/2003

I-20

Shortcut

- In loops like

```
for (int k = 1; k <= 10; k = k + 1) {  
    ...  
}
```

the update "k = k + 1" is so common that Java provides a shorthand way to write it: "k++"
• Equivalent loop

```
for (int k = 1; k <= 10; k++) {  
    ...  
}
```

Double Your Money

- Problem: Suppose you have invested \$1000 at 3% annual interest (meaning that each year, 3% of the present value of the investment is added to it). How many years will it take to double the original investment?
- Analysis: repeatedly increase the investment value by 3% until it reaches \$2000. Count how many times this has to be done.

I-22

A Non-Counting Iteration

- In this problem, the operation needs to be repeated until something happens (value \geq \$2000)
 - We don't know how long this will take
- This is an *indefinite iteration* – the number of repetitions needed is not known in advance
- A while loop is appropriate here

Nested Loops

- How would you print the following figure?

```
*****  
*****  
*****
```

- Useful information:

`System.out.print("");` will print a single ""

`System.out.println("");` will print a single "", then move to the beginning of the next output line

- How would your answer need to be changed if we changed the number of rows or columns?

Another Problem: A Multiplication Table

- How would we print the following table?

```
    1  2  3  4  
1  1  2  3  4  
2  2  4  6  8  
3  3  6  9 12
