Strings, if/else, return, user input

Special thanks to Scott Shawcroft, Ryan Tucker, and Paul Beck for their work on these slides. Except where otherwise noted, this work is licensed under: <u>http://creativecommons.org/licenses/by-nc-sa/3.0</u>

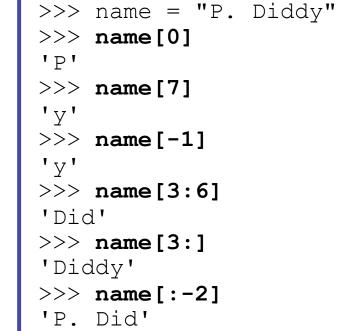

Strings

index	0	1	2	3	4	5	6	7
or	-8	-7	-6	-5	-4	-3	-2	-1
character	Р	•		D	i	d	d	У

- Accessing character(s):
 variable [index]
 variable [index1:index2]
 - index2 is exclusive

Python[™]

 - index1 or index2 can be omitted (end of string)

String Methods

Java	Python
length	len(str)
startsWith, endsWith	startswith, endswith
toLowerCase, toUpperCase	upper, lower, isupper, islower, capitalize, swapcase
indexOf	find
trim	strip

```
>>> name = "Jordan Hiroshi Nakamura"
>>> name.upper()
'JORDAN HIROSHI NAKAMURA'
>>> name.lower().startswith("jordan")
True
>>> len(name)
23
```

net pyt

3

for Loops and Strings

- A for loop can examine each character in a string in order.
 - for name in string: statements

>>> for 	c in "booyah": print(c)
b	
0	
0	
У	
a	
h	

input

input : Reads a string from the user's keyboard.

- reads and returns an entire line of input

```
>>> name = input("Howdy. What's yer name? ")
Howdy. What's yer name? Paris Hilton
>>> name
'Paris Hilton'
```

input for numbers

- to read a number, cast the result of input to an int
 - Only numbers can be cast as ints!
 - Example:

```
age = int(input("How old are you? "))
print("Your age is", age)
print("You have", 65 - age, "years until
retirement")
```

Output:

```
How old are you? <u>53</u>
Your age is 53
You have 12 years until retirement
```

if

if condition: statements

```
- Example:
```

```
gpa = int(input("What is your GPA? "))
```

```
if gpa > 2.0:
```

```
print("Your application is accepted.")
```

if condition: statements elif condition: statements

else:

statements

- Example: gpa = int(input("What is your GPA? ")) if gpa > 3.5: print("You have qualified for the honor roll.") elif gpa > 2.0: print("Welcome to Moon University!") else: print("Apply again in Spring.")

₽ python[™]

if ... in

if value in sequence: statements

- The sequence can be a range, string, tuple, or list

- Examples:

```
x = 3
if x in range(0, 10):
    print("x is between 0 and 9")
name = input("What is your name? ")
name = name.lower()
if name[0] in "aeiou":
    print("Your name starts with a vowel!")
```

Logical Operators

Operator	Meaning	Example	Result
==	equals	1 + 1 == 2	True
! =	does not equal	3.2 != 2.5	True
<	less than	10 < 5	False
>	greater than	10 > 5	True
<=	less than or equal to	126 <= 100	False
>=	greater than or equal to	5.0 >= 5.0	True

Operator	Example	Result
and	(2 == 3) and $(-1 < 5)$	False
or	(2 == 3) or $(-1 < 5)$	True
not	not (2 == 3)	True

Cryptography

EASY

- Caesar Cypher
- ROT-13

HARD

- Diffie-Hellman
- RSA encryption
 - Rivest-Shamir-Adelman

Caesar Cypher

"the cake is a lie"

BECOMES

"wkh fdnh lv d olh!"

- >>> alphabet = 'abcdefghijklmnopqrstuvwxyz'
- >>> alphabet2 = 'defghijklmnopqrstuvwxyzabc'
- >>> substitute(alphabet, alphabet2, "the cake is a lie")
 'wkh fdnh lv d olh`

Write a method substitute, that takes two alphabets and a message, and returns an encoded message

Solution

```
def substitute(text, alphabet1, alphabet2):
    result = ""
    for ch in text:
        if ch in alphabet1:
            result += alphabet
2[alphabet1.find(ch)]
        else:
            result += ch
    return result
```

hahuflvh (exercise)

• The Caesar Cypher is easy to crack...

>>> make_phrase("zebras")
 'zebrascdfghijklmnopqtuvwxy'

Write a method called make_phrase, that takes a phrase and creates a new alphabet

- It might be nice to have something that doesn't require two separate alphabets as parameters.
 - If we were to actually use one of the two cyphers, we'd need the original alphabet, and the changed alphabet.
- Is there a way to encode a message without needing both alphabets?
 - Maybe just using the normal one? (abcdefghijklmnopqrstuvwxyz)

abcdefghijklmnopqrstuvwxyz \rightarrow nopqrstuvwxyzabcdefghijklm

- Everything is shifted 13 letters.
 - Why is this cool?

Strings, if/else, return, user input

Special thanks to Scott Shawcroft, Ryan Tucker, and Paul Beck for their work on these slides. Except where otherwise noted, this work is licensed under: <u>http://creativecommons.org/licenses/by-nc-sa/3.0</u>

Huh?

gur zntvp jbeqf ner fdhrnzvfu bffvsentr

Using the ROT-13 cypher... we get

the magic words are squeamish ossifrage

Wrap up

- Notice how in all the different ways of encoding phrases that we did, both people had to know a "secret".
 - ROT13: you had to know that the alphabet was shifted by 13 letters.
 - Caesar Cypher: You had to know that the alphabet was shifted by 3 letters.
 - Our own "zebras" cypher: You had to know the word "zebras"
- More advanced encryptions like Diffie-Hellman and RSA encryption use the concept of a "secret" number in order to decode the messages.

Formatting Text

"format string" % (parameter, parameter, ...)

- *Placeholders* insert <u>formatted values</u> into a string:
 - an integer - %d a real number – %f - %S a string an integer, 8 characters wide, right-aligned - %8d an integer, 8 characters wide, padding with 0s - %08d - %**-**8d an integer, 8 characters wide, left-aligned a real number, 12 characters wide - %12f - %.4f a real number, 4 characters after decimal a real number, 6 total characters wide, 2 after decimal - %6.2f

>>> x = 3; y = 3.14159; z = "hello"
>>> print("%-8s, %04d is close to %.3f" % (z, x, y))
hello , 0003 is close to 3.142
