# Building Java Programs 

Chapter 5<br>Lecture 5-1: while Loops, Fencepost Loops, and Sentinel Loops

reading: 4.1, 5.1<br>self-check: Ch. 4 \#2; Ch. 5 \# 1-10<br>exercises: Ch. 4 \#2, 4, 5, 8; Ch. 5 \# 1-2

## A deceptive problem...

- Write a method printNumbers that prints each number from 1 to a given maximum, separated by commas.

For example, the call:

printNumbers(5)

should print:

$$
1,2,3,4,5
$$

## Flawed solutions

- public static void printNumbers (int max) \{

$$
\text { for (int } i=1 ; i<=\max ; i++ \text { ) }\{
$$ System.out.print(i + ", ");

\}
System.out.println(); // to end the line of output \}

- Output from printNumbers (5): 1, 2, 3, 4, 5,
- public static void printNumbers(int max) \{ for (int $i=1 ; i<=m a x ; i++)\{$ System.out.print(", " + i); \}
System.out.println(); // to end the line of output \}
- Output from printNumbers (5): , 1, 2, 3, 4, 5

## Fence post analogy

- We print $n$ numbers but need only $n-1$ commas.
- Similar to building a fence with wires separated by posts:
- If we repeatedly place a post + wire, the last post will have an extra dangling wire.
- A flawed algorithm:
for (length of fence) \{
place a post.
place some wire.
\}

## Fencepost loop

- Add a statement outside the loop to place the initial "post."
- Also called a fencepost loop or a "loop-and-a-half" solution.
- The revised algorithm:
place a post.
for (length of fence - 1) \{
place some wire.
place a post.
\}

## Fencepost method solution

```
public static void printNumbers(int max) {
    System.out.print(1);
    for (int i = 2; i <= max; i++) {
    }
    System.out.println(); // to end the line
}
```

- Alternate solution: Either first or last "post" can be taken out:

```
public static void printNumbers(int max) {
    for (int i = 1; i <= max - 1; i++) {
        System.out.print(i + ", ");
    }
    System.out.println(max); // to end the line
}
```

## Fencepost question

- Write a method printPrimes that prints all prime numbers up to a given maximum in the following format.
- Example: printPrimes (50) prints
$\left[\begin{array}{lllllllllllll}2 & 3 & 5 & 7 & 11 & 13 & 17 & 19 & 23 & 29 & 31 & 37 & 41 \\ 43 & 47\end{array}\right]$
- To find primes, write a method countFactors which returns the number of factors of an integer.
- countFactors (60) returns 12 because $1,2,3,4,5,6,10,12,15,20,30$, and 60 are factors of 60.

## Fencepost answer

```
public class Primes {
public static void main(String[] args) {
    printPrimes(50);
    printPrimes(1000);
}
// Prints all prime numbers up to the given max.
public static void printPrimes(int max) {
    System.out.print("[2");
    for (int i = 3; i <= max; i++) {
        if (countFactors(i) == 2) {
        System.out.print(" " + i);
        }
        }
    System.out.println("]");
}
```

## Fencepost answer, continued

```
// Returns how many factors the given number has.
    // Note: this is also in ch04-1 slides
    public static int countFactors(int number) {
    int count = 0;
        for (int i = 1; i <= number; i++) {
            if (number % i == 0) {
                                count++; // i is a factor of number
            }
        }
        return count;
    }
```

\}

## while loops

reading: 5.1<br>self-check: 1-10<br>exercises: 1-2

## Categories of loops

- definite loop: Executes a known number of times.
- The for loops we have seen are definite loops.
- Examples:
- Print "hello" 10 times.
- Find all the prime numbers up to an integer $n$.
- Print each odd number between 5 and 127.
- indefinite loop: One where the number of times its body repeats is not known in advance.
- Examples:
- Prompt the user until they type a non-negative number.
- Print random numbers until a prime number is printed.
- Repeat until the user has types "q" to quit.

## The while loop

- while loop: Repeatedly executes its body as long as a logical test is true.

```
while (test) {
    statement(s);
}
```

- Example:

```
int num = 1;
while (num <= 200) {
    System.out.print(num + " ");
    num = num * 2;
}
```

- OUTPUT:
$\begin{array}{llllllll}1 & 2 & 4 & 8 & 16 & 32 & 64 & 128\end{array}$

## Example while loop

```
// finds a number's first factor other than 1
Scanner console = new Scanner(System.in);
System.out.print("Type a number: ");
int number = console.nextInt();
int factor = 2;
while (number % factor != 0) {
    factor++;
}
System.out.println("First factor: " + factor);
```

- Example log of execution:

Type a number: 91
First factor: 7

- while is better than for here because we don't know how many times we will need to increment to find the factor.

## for Vs. while loops

- The for loop is just a specialized form of the while loop.
- The following loops are equivalent:

```
for (int num = 1; num <= 200; num = num * 2) {
    System.out.print(num + " ");
}
// actually, not a very compelling use of a while loop
// (a for loop is better because the # of reps is definite)
int num = 1;
while (num <= 200) {
    System.out.print(num + " ");
    num = num * 2;
}
```

## while and Scanner

- while loops are often used with scanner input.
- You don't know many times you'll need to re-prompt the user if they type bad data. (an indefinite loop!)
- Write code that repeatedly prompts until the user types a non-negative number, then computes its square root.
- Example log of execution:

```
Type a non-negative integer: -5
Invalid number, try again: -1
Invalid number, try again: -235
Invalid number, try again: -87
Invalid number, try again: 121
The square root of }121\mathrm{ is 11.0
```

## while loop answer

```
System.out.print("Type a non-negative integer: ");
int number = console.nextInt();
while (number < 0) {
    System.out.print("Invalid number, try again: ");
    number = console.nextInt();
}
System.out.println("The square root of " + number +
                        " is " + Math.sqrt(number));
```

- Notice that number has to be declared outside the loop.

# Sentinel loops 

reading: 5.1<br>self-check: 5<br>exercises: 1, 2<br>videos: Ch. 5 \#4

## Sentinel values

- sentinel: A value that signals the end of user input.
- sentinel loop: Repeats until a sentinel value is seen.
- Example: A program that repeatedly prompts the user for numbers until the user types -1 , then outputs their sum.
- (In this case, -1 is the sentinel value.)

```
Enter a number (-1 to quit): 10
Enter a number (-1 to quit): 255
Enter a number (-1 to quit): 35
Enter a number (-1 to quit): -1
The sum is }7
```

## A second sentinel problem

- Exercise: Write a program that repeatedly prompts the user for words until the user types "goodbye", then outputs the longest word that was typed.
- (In this case, "goodbye" is the sentinel value.)

```
Type a word (or "goodbye" to quit): Obama
Type a word (or "goodbye" to quit): McCain
Type a word (or "goodbye" to quit): Biden
Type a word (or "goodbye" to quit): Palin
Type a word (or "goodbye" to quit): goodbye
The longest word you typed was "McCain" (6 letters)
```

## Flawed sentinel solution

- What's wrong with this solution?

```
Scanner console = new Scanner(System.in);
String longest = "";
String word = ""; // "dummy value"; anything but "goodbye"
while (!word.equals("goodbye")) {
    System.out.print("Type a word (or \"goodbye\" to quit): ");
    word = console.next();
    if (word.length() > longest.length()) {
    longest = word;
    }
}
System.out.println("The longest word you typed was \"" +
    longest + "\" (" + longest.length() + " letters)");
```

- The solution produces the wrong output!

The longest word you typed was "goodbye" (7 letters)

## The problem

- Our code uses a pattern like this: longest = empty string. while (input is not the sentinel) \{ prompt for input; read input. check if input is longest; if so, store it. \}
- On the last pass, the sentinel is added to the sum: prompt for input; read input ("goodbye"). check if input is longest; if so, store it.
- This is a fencepost problem.
- We must read $N$ words, but only process the first $N-1$ of them.

## A fencepost solution

- We need to use a pattern like this:

```
longest = empty string. prompt for input; read input.
```

// place 1st "post"
while (input is not the sentinel) \{ check if input is longest; if so, store it. // place a "wire" prompt for input; read input.
// place a "post" \}

- Sentinel loops often utilize a fencepost "loop-and-a-half" solution by pulling some code out of the loop.

## Correct code

- This solution produces the correct output:

```
Scanner console = new Scanner(System.in);
String longest = "";
// moved one "post" out of loop
System.out.print("Type a word (or \"goodbye\" to quit): ");
String word = console.next();
while (!word.equals("goodbye")) {
    if (word.length() > longest.length()) {
        longest = word; // moved to top of loop
    }
    System.out.print("Type a word (or \"goodbye\" to quit): ");
    word = console.next();
}
System.out.println("The longest word you typed was \"" + longest + "\" (" + longest.length() + " letters)");
```

## Constant with sentinel

- A better solution uses a constant for the sentinel: public static final String SENTINEL = "goodbye";
- This solution uses the constant:

```
Scanner console = new Scanner(System.in);
System.out.print("Type a word (or \"" + SENTINEL + "\" to quit): ");
String word = console.next();
String longest = "";
while (!word.equals(SENTINEL)) {
    if (word.length() > longest.length()) {
        longest = word; // moved to top of loop
    }
    System.out.print("Type a word (or \"" + SENTINEL + "\" to quit): ");
    word = console.next();
}
System.out.println("The longest word you typed was \"" + longest + "\" (" + longest.length() + " letters)");
```

## Sentinel number problem

- Solution to the "sum numbers until-1 is typed" problem:

```
Scanner console = new Scanner(System.in);
int sum = 0;
System.out.print("Enter a number (-1 to quit): ");
int number = console.nextInt();
while (number != -1) {
        sum = sum + number; // moved to top of loop
        System.out.print("Enter a number (-1 to quit): ");
        number = console.nextInt();
}
System.out.println("The sum is " + sum);
```
