

Building Java Programs

Chapter 3
Lecture 7: Return values, Math, and double

reading: 3.2, 2.1 - 2.2

Java's Math class

Method name	Description
Math.abs(<i>value</i>)	absolute value
Math.ceil(<i>value</i>)	rounds up
Math.floor(<i>value</i>)	rounds down
Math.log10(<i>value</i>)	logarithm, base 10
Math.max(<i>value1, value2</i>)	larger of two values
Math.min(<i>value1, value2</i>)	smaller of two values
Math.pow(<i>base, exp</i>)	<i>base</i> to the <i>exp</i> power
Math.random()	random double between 0 and 1
Math.round(<i>value</i>)	nearest whole number
Math.sqrt(<i>value</i>)	square root
Math.sin(<i>value</i>) Math.cos(<i>value</i>) Math.tan(<i>value</i>)	sine/cosine/tangent of an angle in radians
Math.toDegrees(<i>value</i>) Math.toRadians(<i>value</i>)	convert degrees to radians and back

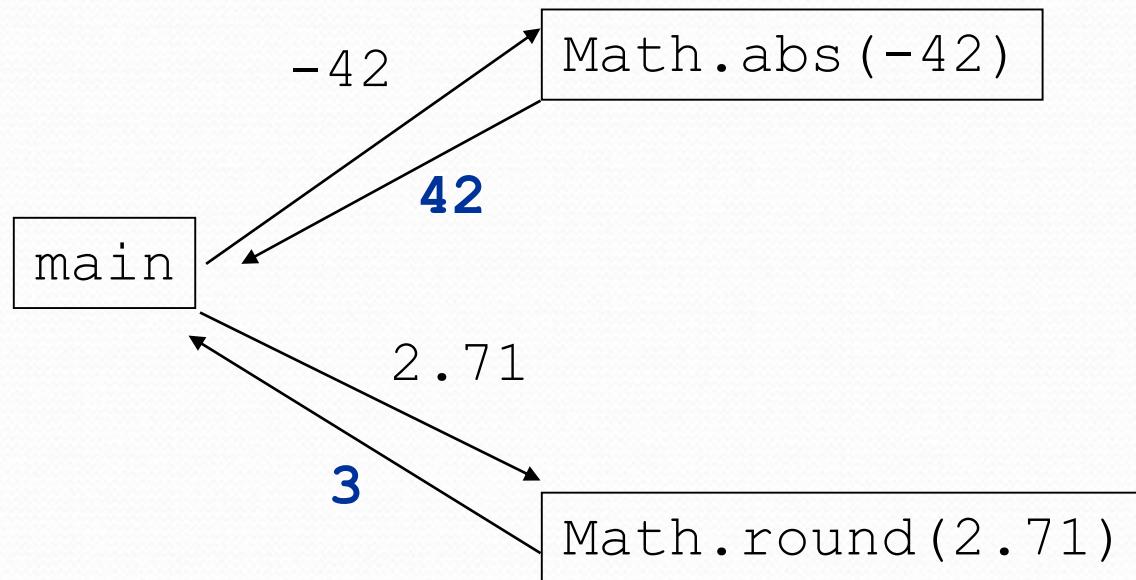

Constant	Description
Math.E	2.7182818...
Math.PI	3.1415926...

No output?

- Simply calling these methods produces no visible result.
 - `Math.pow(3, 4); // no output`
- Math method calls use a Java feature called *return values* that cause them to be treated as expressions.
- The program runs the method, computes the answer, and then "replaces" the call with its computed result value.
 - ~~`Math.pow(3, 4); // no output`~~
`81.0; // no output`
- To see the result, we must print it or store it in a variable.
 - `double result = Math.pow(3, 4);`
 - `System.out.println(result); // 81.0`

Return

- **return**: To send out a value as the result of a method.
 - Return values send information *out* from a method to its caller.
 - A call to the method can be used as part of an expression.
 - (Compare to parameters which send values *into* a method)

Math questions

- Evaluate the following expressions:
 - `Math.abs(-1.23)`
 - `Math.pow(3, 2)`
 - `Math.pow(10, -2)`
 - `Math.sqrt(121.0) - Math.sqrt(256.0)`
 - `Math.round(Math.PI) + Math.round(Math.E)`
 - `Math.ceil(6.022) + Math.floor(15.9994)`
 - `Math.abs(Math.min(-3, -5))`
- `Math.max` and `Math.min` can be used to bound numbers.
Consider an `int` variable named `age`.
 - What statement would replace negative ages with 0?
 - What statement would cap the maximum age to 40?

Why return and not print?

- It might seem more useful for the `Math` methods to print their results rather than returning them. Why don't they?
- Answer: Returning is more flexible than printing.
 - We can compute several things before printing:

```
double pow1 = Math.pow(3, 4);
double pow2 = Math.pow(10, 6);
System.out.println("Powers are " + pow1 + " and " + pow2);
```

- We can combine the results of many computations:

```
double k = 13 * Math.pow(3, 4) + 5 - Math.sqrt(17.8);
```

Returning a value

```
public static type name(parameters) {  
    statements;  
    ...  
    return expression;  
}
```

- When Java reaches a return statement:
 - it evaluates the expression
 - it substitutes the return value in place of the call
 - it goes back to the caller and continues after the method call

Return examples

// Converts degrees Fahrenheit to Celsius.

```
public static double fToC(double degreesF) {  
    double degreesC = 5.0 / 9.0 * (degreesF - 32);  
    return degreesC;  
}
```

// Computes triangle hypotenuse length given its side lengths.

```
public static double hypotenuse(int a, int b) {  
    double c = Math.sqrt(a * a + b * b);  
    return c;  
}
```

- You can shorten the examples by returning an expression:

```
public static double fToC(double degreesF) {  
    return 5.0 / 9.0 * (degreesF - 32);  
}
```

Common error: Not storing

- Many students incorrectly think that a `return` statement sends a variable's name back to the calling method.

```
public static void main(String[] args) {  
    slope(0, 0, 6, 3);  
    System.out.println("The slope is " + result); // ERROR:  
}                                              // cannot find symbol: result
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

Fixing the common error

- Returning sends the variable's *value* back. Store the returned value into a variable or use it in an expression.

```
public static void main(String[] args) {  
    double s = slope(0, 0, 6, 3);  
    System.out.println("The slope is " + s);  
}
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

Quirks of real numbers

- Some Math methods return double or other non-int types.

```
int x = Math.pow(10, 3);    // ERROR: incompat. types
```

- Some double values print poorly (too many digits).

```
double result = 1.0 / 3.0;  
System.out.println(result);    // 0.3333333333333333
```

- The computer represents doubles in an imprecise way.

```
System.out.println(0.1 + 0.2);
```

- Instead of 0.3, the output is 0.3000000000000004

Type casting

- **type cast:** A conversion from one type to another.
 - To promote an `int` into a `double` to get exact division from `/`
 - To truncate a `double` from a real number to an integer
- Syntax:
(type) expression

Examples:

```
double result = (double) 19 / 5;           // 3.8
int result2 = (int) result;                 // 3
int x = (int) Math.pow(10, 3);             // 1000
```

More about type casting

- Type casting has high precedence and only casts the item immediately next to it.
 - `double x = (double) 1 + 1 / 2; // 1.0`
 - `double y = 1 + (double) 1 / 2; // 1.5`
- You can use parentheses to force evaluation order.
 - `double average = (double) (a + b + c) / 3;`
- A conversion to double can be achieved in other ways.
 - `double average = 1.0 * (a + b + c) / 3;`

Exercise

- In physics, the *displacement* of a moving body represents its change in position over time while accelerating.
 - Given initial velocity v_0 in m/s, acceleration a in m/s², and elapsed time t in s, the displacement of the body is:
 - Displacement = $v_0 t + \frac{1}{2} a t^2$
- Write a method `displacement` that accepts v_0 , a , and t and computes and returns the change in position.
 - example: `displacement(3.0, 4.0, 5.0)` returns 65.0

Exercise solution

```
public static double displacement(double v0, double a, double t) {  
    double d = v0 * t + 0.5 * a * Math.pow(t, 2);  
    return d;  
}
```

Exercise

- If you drop two balls, which will hit the ground first?
 - Ball 1: height of 600m, initial velocity = 25 m/sec downward
 - Ball 2: height of 500m, initial velocity = 15 m/sec downward
- Write a program that determines how long each ball takes to hit the ground (and draws each ball falling).
- Total time is based on the force of gravity on each ball.
 - Acceleration due to gravity $\approx 9.81 \text{ m/s}^2$, downward
 - Displacement = $v_0 t + \frac{1}{2} a t^2$

Ball solution

```
// Simulates the dropping of two balls from various heights.  
import java.awt.*;  
  
public class Balls {  
    public static void main(String[] args) {  
        DrawingPanel panel = new DrawingPanel(600, 600);  
        Graphics g = panel.getGraphics();  
  
        int ball1x = 100, ball1y = 0, v01 = 25;  
        int ball2x = 200, ball2y = 100, v02 = 15;  
  
        // draw the balls at each time increment  
        for (double t = 0; t <= 10.0; t = t + 0.1) {  
            double disp1 = displacement(v01, t, 9.81);  
            g.fillOval(ball1x, ball1y + (int) disp1, 10, 10);  
            double disp2 = displacement(v02, t, 9.81);  
            g.fillOval(ball2x, ball2y + (int) disp2, 10, 10);  
  
            panel.sleep(50); // pause for 50 ms  
            panel.clear();  
        }  
    }  
    ...
```
