

# CSE 142, Winter 2018

## Programming Assignment #4: Gradanator (20 points)

Due Tuesday, January 30, 2018 9:00 PM

This interactive program focuses on `if/else` statements, `Scanner`, and returning values. Turn in a file named `Gradanator.java`. To use a `Scanner` for console input, you must `import java.util.*;` in your code. The program prompts a student for grades on homework and two exams and uses them to compute the student's course grade.

Below is one example log of execution from the program. This program behaves differently depending on the user input; user input is bold and underlined below to make it stand out. Your output should match our examples exactly given the same input. (Be mindful of spacing, such as after input prompts and between output sections.) **Look at the other example logs on the course web site** and on the next page to get more examples of the program's behavior.

```
This program reads exam/homework scores
and reports your overall course grade.

Midterm:
Weight (0-100)? 20
Score earned? 78
Were scores shifted (1=yes, 2=no)? 2
Total points = 78 / 100
Weighted score = 15.6 / 20

Final:
Weight (0-100)? 35
Score earned? 95
Were scores shifted (1=yes, 2=no)? 1
Shift amount? 10
Total points = 100 / 100
Weighted score = 35.0 / 35

Homework:
Weight (0-100)? 45
Number of assignments? 3
Assignment 1 score and max? 18 20
Assignment 2 score and max? 29 32
Assignment 3 score and max? 31 40
How many sections did you attend? 4
Section points = 20 / 30
Total points = 98 / 122
Weighted score = 36.1 / 45

Overall percentage = 86.7
Your grade will be at least: 3.0
<< your custom grade message here >>
```

The program begins with an introduction message that briefly explains the program. The program then reads scores in three categories: midterm, homework and final. Each category is weighted: its points are scaled up to a fraction of the 100 percent grade for the course. As the program begins reading each category, it first prompts for the category's weight.

The user begins by entering scores earned on the midterm. The program asks whether exam scores were shifted, interpreting an answer of 1 to mean "yes" and 2 to mean "no." If there is a shift, the program prompts for the shift amount, and the shift is added to the user's midterm score. Exam scores are capped at a max of 100; for example, if the user got 95 and there was a shift of 10, the score to use would be 100. The midterm's "weighted score" is printed, which is equal to the user's score multiplied by the exam's weight.

Next, the program prompts for data about the final. This behavior is the same as the behavior for the midterm.

Next, the user enters information about his/her homework, including the weight and how many assignments were given. For each assignment, the user enters a score and points possible. Use a **cumulative sum** as in textbook section 4.2.

Section attendance is included in the homework category. You should assume that each section attended is worth 5 points, up to a maximum of 30 points. This means that section points are capped to 30 before they are added to the homework category.

Once the program has read the user information for both exams and homework, it prints the student's overall percentage earned in the course, which is the sum of the weighted scores from the three categories, as shown below:

$$Grade = WeightedMidtermScore + WeightedFinalExamScore + WeightedHomeworkScore$$

$$Grade = \left( \frac{78}{100} \times 20 \right) + \left( \frac{100}{100} \times 35 \right) + \left( \frac{18 + 29 + 31 + (4 \times 5)}{20 + 32 + 40 + 30} \times 45 \right)$$

$$Grade = 15.6 + 35.0 + 36.1475411$$

$$Grade = round(86.7475411) = 86.7$$

The program prints a loose guarantee about a minimum grade on the 4.0-scale the student will get in the course, based on the following scale. See the logs of execution on the course web site to see the expected output for each grade range, but note that these numbers here are simplified compared to the guarantees on the syllabus.

**85% and above:** 3.0;    **84.99% - 75%:** 2.0;    **74.99% - 60%:** 0.7;    **under 60%:** 0.0

After printing the guaranteed minimum grade, print a custom message of your choice about the grade. This message should be different for each grade range shown above. It should be at least 1 line of any non-offensive text you like.

This program processes user input using a `Scanner`. You should handle the following two special cases of input:

- A student can receive extra credit on an *individual assignment*, but **the total points for homework are capped at the maximum possible**. For example, a student who earns 41/40, 39/40, and 47/40 on three assignments, and 25/30 on section attendance will receive 150 homework points (the max) even though they earned 152. Sections points are capped at 30.
- **Cap exam scores at 100**. If the raw or shifted exam score exceeds 100, a score of 100 is used.

Otherwise, you may assume the user enters **valid input**. When prompted for a value, the user will enter an integer in the proper range. The user will enter a number of homework assignments  $\geq 1$ , and the sum of the three weights will be exactly 100. The weight of each category will be a non-negative number. Exam shifts will be  $\geq 0$ .

## Development Strategy and Hints:

- Tackle parts of the program (midterm, homework, final exam) one at a time, rather than writing the entire program at once. Write a bit of code, get it to compile, and test what you have so far. If you try to write large amounts of code without attempting to compile it, you may encounter a large list of compiler errors and/or bugs.
- To compute homework scores, you will need to cumulatively sum not only the total points the student has earned, but also the total points possible on all homework assignments. See textbook section 4.2 about cumulative sums.
- The homework part reads two values on one line from the `Scanner`. See the lecture slides for an example of this.
- Many students get "cannot find symbol" compiler errors. Common mistakes include forgetting to pass / return a needed value, forgetting to store a returned value into a variable, and referring to a variable by the wrong name.
- All weighted scores and grades are printed with no more than 1 digit after the decimal point. Achieve this with a custom method or `System.out.printf`. The following code prints variable `x` rounded to the nearest tenth:

```
double x = 1.2345;
System.out.printf("x is around %.1f in size.\n", x); // 1.2
```
- If you are getting scores of 0 regardless of what data the user types, you may have a problem with integer division. See Chapter 2 about types `int` and `double`, type-casting, and how to avoid integer division problems. If you have a value of type `double` but need to convert it into an `int`, use a type-cast such as the following:

```
double d = 5.678;
int i = (int) d; // 5
```
- Use `Math.max` and `Math.min` to constrain numbers to within a particular bound.

## Style Guidelines:

For this assignment, you are limited to Java features from Ch. 1-4. A major part of this assignment is demonstrating that you understand parameters and return values. Use static methods, parameters, and returns for structure and to eliminate redundancy. For full credit, use **at least 4 non-trivial methods** other than `main`. For reference, our solution is roughly 110 lines long (66 "substantive"), with 6 methods other than `main`, though you do not need to match this.

Like on previous assignments, you should not have `println` statements in your main method. Also, `main` should be a concise summary of the overall program; `main` should make calls to several of your other methods that implement the majority of the program's behavior. Your methods will need to make appropriate use of parameters and return values. Each method should perform a coherent task and should not do too large a share of the overall work. Avoid lengthy "chaining" of method calls, where each method calls the next, no values are returned, and control does not come back to `main`. (See textbook Chapter 4's case study for a discussion of well-designed versus poorly designed methods.)

This document describes several numbers that are important to the overall program. For full credit, **you should make at least one of such numbers into a class constant** so that the constant could be changed and your program would adapt.

When handling numeric data, you are expected to choose appropriately between types `int` and `double`. You will lose points if you use type `double` for variables in cases where type `int` would be more appropriate.

Some of your code will use conditional execution with `if` and `if/else` statements. Part of your grade will come from using these statements properly. Review book sections 4.1-4.3 about nested `if/else` statements and factoring them.

Give meaningful names to methods and variables, and use proper indentation and whitespace. Follow Java's naming standards as specified in Chapter 1. Localize variables when possible; declare them in the smallest scope needed. Include meaningful comment headers including identifying information like your name, section, TA name, date, etc at the top of your program and at the start of each method. Limit line lengths to 100 chars.
